In many situations, the migration of C code to Ada is justified by an increase in terms of integrity expectations, in which case it's expected that development costs will rise. However, Ada is a more expressive, powerful language, designed to reduce errors earlier in the life-cycle, thus reducing costs. Therefore, Ada makes it possible to write very safe and secure software at a lower cost than languages such as C.

CHAPTER

NINETYONE

APPENDIX A: HANDS-ON OBJECT-ORIENTED PROGRAMMING

The goal of this appendix is to present a hands-on view on how to translate a system from C to Ada and improve it with object-oriented programming.

91.1 System Overview

Let's start with an overview of a simple system that we'll implement and use below. The main system is called AB and it combines two systems A and B. System AB is not supposed to do anything useful. However, it can serve as a good model for the hands-on we're about to start.

This is a list of requirements for the individual systems A and B, and the combined system AB:

- System A:
  - The system can be activated and deactivated.
    - During activation, the system's values are reset.
  - Its current value (in floating-point) can be retrieved.
    - This value is the average of the two internal floating-point values.
  - Its current state (activated or deactivated) can be retrieved.
- System B:
  - The system can be activated and deactivated.
    - During activation, the system's value is reset.
  - Its current value (in floating-point) can be retrieved.
  - Its current state (activated or deactivated) can be retrieved.
- System AB
  - The system contains an instance of system A and an instance of system B.
  - The system can be activated and deactivated.
    - System AB activates both systems A and B during its own activation.
    - System AB deactivates both systems A and B during its own deactivation.
  - Its current value (in floating-point) can be retrieved.
    - This value is the average of the current values of systems A and B.
  - Its current state (activated or deactivated) can be retrieved.
    - AB is only considered activated when both systems A and B are activated.

- The system's health can be checked.
  - This check consists in calculating the absolute difference D between the current values of systems A and B and checking whether D is below a threshold of 0.1.

The source-code in the following section contains an implementation of these requirements.

91.2 Non Object-Oriented Approach

In this section, we look into implementations (in both C and Ada) of system AB that don't make use of object-oriented programming.

91.2.1 Starting point in C

Let's start with an implementation in C for the system described above:

[C]

Listing 2584: system_a.h

```c
typedef struct {
    float val[2];
    int   active;
} A;

void A_activate (A *a);

int A_is_active (A *a);

float A_value (A *a);

void A_deactivate (A *a);
```

Listing 2585: system_a.c

```c
#include "system_a.h"

void A_activate (A *a)
{
    int i;

    for (i = 0; i < 2; i++)
    {
        a->val[i] = 0.0;
    }
    a->active = 1;
}

int A_is_active (A *a)
{
    return a->active == 1;
}

float A_value (A *a)
{
    return (a->val[0] + a->val[1]) / 2.0;
}

void A_deactivate (A *a)
{
```

(continues on next page)

(continued from previous page)

```
    a->active = 0;
}
```

Listing 2586: system_b.h

```
typedef struct {
    float val;
    int   active;
} B;

void B_activate (B *b);

int B_is_active (B *b);

float B_value (B *b);

void B_deactivate (B *b);
```

Listing 2587: system_b.c

```
#include "system_b.h"

void B_activate (B *b)
{
    b->val    = 0.0;
    b->active = 1;
}

int B_is_active (B *b)
{
    return b->active == 1;
}

float B_value (B *b)
{
    return b->val;
}

void B_deactivate (B *b)
{
    b->active = 0;
}
```

Listing 2588: system_ab.h

```
#include "system_a.h"
#include "system_b.h"

typedef struct {
    A a;
    B b;
} AB;

void AB_activate (AB *ab);

int AB_is_active (AB *ab);

float AB_value (AB *ab);

int AB_check (AB *ab);
```

(continues on next page)

(continued from previous page)

```

void AB_deactivate (AB *ab);
```

Listing 2589: system_ab.c

```
#include <math.h>
#include "system_ab.h"

void AB_activate (AB *ab)
{
    A_activate (&ab->a);
    B_activate (&ab->b);
}

int AB_is_active (AB *ab)
{
    return A_is_active(&ab->a) && B_is_active(&ab->b);
}

float AB_value (AB *ab)
{
    return (A_value (&ab->a) + B_value (&ab->b)) / 2;
}

int AB_check (AB *ab)
{
    const float threshold = 0.1;

    return fabs (A_value (&ab->a) - B_value (&ab->b)) < threshold;
}

void AB_deactivate (AB *ab)
{
    A_deactivate (&ab->a);
    B_deactivate (&ab->b);
}
```

Listing 2590: main.c

```
#include <stdio.h>
#include "system_ab.h"

void display_active (AB *ab)
{
    if (AB_is_active (ab))
        printf ("System AB is active.\n");
    else
        printf ("System AB is not active.\n");
}

void display_check (AB *ab)
{
    if (AB_check (ab))
        printf ("System AB check: PASSED.\n");
    else
        printf ("System AB check: FAILED.\n");
}

int main()
{
```

(continues on next page)

(continued from previous page)

```
    AB s;

    printf ("Activating system AB...\n");
    AB_activate (&s);

    display_active (&s);
    display_check (&s);

    printf ("Deactivating system AB...\n");
    AB_deactivate (&s);

    display_active (&s);
}
```

Code block metadata

```
Project: Courses.Ada_For_Embedded_C_Dev.HandsOnOOP.System_AB_C
MD5: 649bcfe39504c853a0c3f43e1e048f34
```

Runtime output

```
Activating system AB...
System AB is active.
System AB check: PASSED.
Deactivating system AB...
System AB is not active.
```

Here, each system is implemented in a separate set of header and source-code files. For example, the API of system AB is in `system_ab.h` and its implementation in `system_ab.c`.

In the main application, we instantiate system AB and activate it. Then, we proceed to display the activation state and the result of the system's health check. Finally, we deactivate the system and display the activation state again.

91.2.2 Initial translation to Ada

The direct implementation in Ada is:

[Ada]

Listing 2591: system_a.ads

```ada
package System_A is

   type Val_Array is array (Positive range <>) of Float;

   type A is record
      Val    : Val_Array (1 .. 2);
      Active : Boolean;
   end record;

   procedure A_Activate (E : in out A);

   function A_Is_Active (E : A) return Boolean;

   function A_Value (E : A) return Float;

   procedure A_Deactivate (E : in out A);

end System_A;
```

Listing 2592: system_a.adb

```
package body System_A is

   procedure A_Activate (E : in out A) is
   begin
      E.Val    := (others => 0.0);
      E.Active := True;
   end A_Activate;

   function A_Is_Active (E : A) return Boolean is
   begin
      return E.Active;
   end A_Is_Active;

   function A_Value (E : A) return Float is
   begin
      return (E.Val (1) + E.Val (2)) / 2.0;
   end A_Value;

   procedure A_Deactivate (E : in out A) is
   begin
      E.Active := False;
   end A_Deactivate;

end System_A;
```

Listing 2593: system_b.ads

```
package System_B is

   type B is record
      Val    : Float;
      Active : Boolean;
   end record;

   procedure B_Activate (E : in out B);

   function B_Is_Active (E : B) return Boolean;

   function B_Value (E : B) return Float;

   procedure B_Deactivate (E : in out B);

end System_B;
```

Listing 2594: system_b.adb

```
package body System_B is

   procedure B_Activate (E : in out B) is
   begin
      E.Val    := 0.0;
      E.Active := True;
   end B_Activate;

   function B_Is_Active (E : B) return Boolean is
   begin
      return E.Active;
   end B_Is_Active;

```

(continues on next page)

(continued from previous page)

```
   function B_Value (E : B) return Float is
   begin
      return E.Val;
   end B_Value;

   procedure B_Deactivate (E : in out B) is
   begin
      E.Active := False;
   end B_Deactivate;

end System_B;
```

Listing 2595: system_ab.ads

```
with System_A; use System_A;
with System_B; use System_B;

package System_AB is

   type AB is record
      SA : A;
      SB : B;
   end record;

   procedure AB_Activate (E : in out AB);

   function AB_Is_Active (E : AB) return Boolean;

   function AB_Value (E : AB) return Float;

   function AB_Check (E : AB) return Boolean;

   procedure AB_Deactivate (E : in out AB);

end System_AB;
```

Listing 2596: system_ab.adb

```
package body System_AB is

   procedure AB_Activate (E : in out AB) is
   begin
      A_Activate (E.SA);
      B_Activate (E.SB);
   end AB_Activate;

   function AB_Is_Active (E : AB) return Boolean is
   begin
      return A_Is_Active (E.SA) and B_Is_Active (E.SB);
   end AB_Is_Active;

   function AB_Value (E : AB) return Float is
   begin
      return (A_Value (E.SA) + B_Value (E.SB)) / 2.0;
   end AB_Value;

   function AB_Check (E : AB) return Boolean is
      Threshold : constant := 0.1;
   begin
      return abs (A_Value (E.SA) - B_Value (E.SB)) < Threshold;
```

(continues on next page)

(continued from previous page)

```
   end AB_Check;

   procedure AB_Deactivate (E : in out AB) is
   begin
      A_Deactivate (E.SA);
      B_Deactivate (E.SB);
   end AB_Deactivate;

end System_AB;
```

Listing 2597: main.adb

```
with Ada.Text_IO; use Ada.Text_IO;

with System_AB;   use System_AB;

procedure Main is

   procedure Display_Active (E : AB) is
   begin
      if AB_Is_Active (E) then
         Put_Line ("System AB is active");
      else
         Put_Line ("System AB is not active");
      end if;
   end Display_Active;

   procedure Display_Check (E : AB) is
   begin
      if AB_Check (E) then
         Put_Line ("System AB check: PASSED");
      else
         Put_Line ("System AB check: FAILED");
      end if;
   end Display_Check;

   S : AB;
begin
   Put_Line ("Activating system AB...");
   AB_Activate (S);

   Display_Active (S);
   Display_Check (S);

   Put_Line ("Deactivating system AB...");
   AB_Deactivate (S);

   Display_Active (S);
end Main;
```

Code block metadata

```
Project: Courses.Ada_For_Embedded_C_Dev.HandsOnOOP.System_AB_Ada
MD5: f2e3df0b3874e5edc5ea90c01961cf64
```

Runtime output

```
Activating system AB...
System AB is active
System AB check: PASSED
Deactivating system AB...
```

(continues on next page)

(continued from previous page)

```
System AB is not active
```

As you can see, this is a direct translation that doesn't change much of the structure of the original C code. Here, the goal was to simply translate the system from one language to another and make sure that the behavior remains the same.

91.2.3 Improved Ada implementation

By analyzing this direct implementation, we may notice the following points:

- Packages `System_A`, `System_B` and `System_AB` are used to describe aspects of the same system. Instead of having three distinct packages, we could group them as child packages of a common parent package — let's call it `Simple`, since this system is supposed to be simple. This approach has the advantage of allowing us to later use the parent package to implement functionality that is common for all parts of the system.
- Since we have subprograms that operate on types `A`, `B` and `AB`, we should avoid exposing the record components by moving the type declarations to the private part of the corresponding packages.
- Since Ada supports subprogram overloading — as discussed in *this section from chapter 2* (page 1958) —, we don't need to have different names for subprograms with similar functionality. For example, instead of having `A_Is_Active` and `B_Is_Active`, we can simply name these functions `Is_Active` for both types `A` and `B`.
- Some of the functions — such as `A_Is_Active` and `A_Value` — are very simple, so we could simplify them with expression functions.

This is an update to the implementation that addresses all the points above:

[Ada]

Listing 2598: simple.ads

```
package Simple
  with Pure
is
end Simple;
```

Listing 2599: simple-system_a.ads

```
package Simple.System_A is

   type A is private;

   procedure Activate (E : in out A);

   function Is_Active (E : A) return Boolean;

   function Value (E : A) return Float;

   procedure Finalize (E : in out A);

private

   type Val_Array is array (Positive range <>) of Float;

   type A is record
      Val    : Val_Array (1 .. 2);
      Active : Boolean;
```

(continues on next page)

Deactivating system AB...
System AB is not active
```

91.3 First Object-Oriented Approach

Until now, we haven't used any of the object-oriented programming features of the Ada language. So we can start by analyzing the API of systems A and B and deciding how to best abstract some of its elements using object-oriented programming.

91.3.1 Interfaces

The first thing we may notice is that we actually have two distinct sets of APIs there:

- one API for activating and deactivating the system.
- one API for retrieving the value of the system.

We can use this distinction to declare two interface types:

- `Activation_IF` for the `Activate` and `Deactivate` procedures and the `Is_Active` function;
- `Value_Retrieval_IF` for the `Value` function.

This is how the declaration could look like:

```
type Activation_IF is interface;

procedure Activate (E : in out Activation_IF) is abstract;
function Is_Active (E : Activation_IF) return Boolean is abstract;
procedure Deactivate (E : in out Activation_IF) is abstract;

type Value_Retrieval_IF is interface;

function Value (E : Value_Retrieval_IF) return Float is abstract;
```

Note that, because we are declaring interface types, all operations on those types must be abstract or, in the case of procedures, they can also be declared `null`. For example, we could change the declaration of the procedures above to this:

```
procedure Activate (E : in out Activation_IF) is null;
procedure Deactivate (E : in out Activation_IF) is null;
```

When an operation is declared abstract, we must override it for the type that derives from the interface. When a procedure is declared `null`, it acts as a do-nothing default. In this case, overriding the operation is optional for the type that derives from this interface.

91.3.2 Base type

Since the original system needs both interfaces we've just described, we have to declare another type that combines those interfaces. We can do this by declaring the interface type Sys_Base, which serves as the base type for systems A and B. This is the declaration:

```
type Sys_Base is interface and Activation_IF and Value_Retrieval_IF;
```

Since the system activation functionality is common for both systems A and B, we could implement it as part of Sys_Base. That would require changing the declaration from a simple interface to an abstract record:

```
type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF
  with null record;
```

Now, we can add the Boolean component to the record (as a private component) and override the subprograms of the Activation_IF interface. This is the adapted declaration:

```
   type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF with private;

   overriding procedure Activate (E : in out Sys_Base);
   overriding function Is_Active (E : Sys_Base) return Boolean;
   overriding procedure Deactivate (E : in out Sys_Base);

private

   type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF with record
      Active : Boolean;
   end record;
```

91.3.3 Derived types

In the declaration of the Sys_Base type we've just seen, we're not overriding the Value function — from the Value_Retrieval_IF interface — for the Sys_Base type, so it remains an abstract function for Sys_Base. Therefore, the Sys_Base type itself remains abstract and needs be explicitly declared as such.

We use this strategy to ensure that all types derived from Sys_Base need to implement their own version of the Value function. For example:

```
type A is new Sys_Base with private;

overriding function Value (E : A) return Float;
```

Here, the A type is derived from the Sys_Base and it includes its own version of the Value function by overriding it. Therefore, A is not an abstract type anymore and can be used to declare objects:

```
procedure Main is
   Obj : A;
   V   : Float;
begin
   Obj.Activate;
   V := Obj.Value;
end Main;
```

Important

Note that the use of the **overriding** keyword in the subprogram declaration is not strictly necessary. In fact, we could leave this keyword out, and the code would still compile. However, if provided, the compiler will check whether the information is correct.

Using the **overriding** keyword can help to avoid bad surprises — when you *may think* that you're overriding a subprogram, but you're actually not. Similarly, you can also write **not overriding** to be explicit about subprograms that are new primitives of a derived type. For example:

```
not overriding function Check (E : AB) return Boolean;
```

We also need to declare the values that are used internally in systems A and B. For system A, this is the declaration:

```
   type A is new Sys_Base with private;

   overriding function Value (E : A) return Float;

private

   type Val_Array is array (Positive range <>) of Float;

   type A is new Sys_Base with record
      Val : Val_Array (1 .. 2);
   end record;
```

91.3.4 Subprograms from parent

In the previous implementation, we've seen that the `A_Activate` and `B_Activate` procedures perform the following steps:

- initialize internal values;
- indicate that the system is active (by setting the `Active` flag to **`True`**).

In the implementation of the `Activate` procedure for the `Sys_Base` type, however, we're only dealing with the second step. Therefore, we need to override the `Activate` procedure and make sure that we initialize internal values as well. First, we need to declare this procedure for type A:

```
type A is new Sys_Base with private;

overriding procedure Activate (E : in out A);
```

In the implementation of `Activate`, we should call the `Activate` procedure from the parent (`Sys_Base`) to ensure that whatever was performed for the parent will be performed in the derived type as well. For example:

```
overriding procedure Activate (E : in out A) is
begin
   E.Val := (others => 0.0);
   Sys_Base (E).Activate;    --  Calling Activate for Sys_Base type:
                             --  this call initializes the Active flag.
end;
```

Here, by writing `Sys_Base (E)`, we're performing a view conversion. Basically, we're telling the compiler to view `E` not as an object of type `A`, but of type `Sys_Base`. When we do this, any operation performed on this object will be done as if it was an object of `Sys_Base` type, which includes calling the `Activate` procedure of the `Sys_Base` type.

Important

If we write `T (Obj).Proc`, we're telling the compiler to call the `Proc` procedure of type `T` and apply it on `Obj`.

If we write `T'Class (Obj).Proc`, however, we're telling the compiler to dispatch the call. For example, if `Obj` is of derived type `T2` and there's an overridden `Proc` procedure for type `T2`, then this procedure will be called instead of the `Proc` procedure for type `T`.

91.3.5 Type AB

While the implementation of systems A and B is almost straightforward, it gets more interesting in the case of system AB. Here, we have a similar API, but we don't need the activation mechanism implemented in the abstract type Sys_Base. Therefore, deriving from Sys_Base is not the best option. Instead, when declaring the AB type, we can simply use the same interfaces as we did for Sys_Base, but keep it independent from Sys_Base. For example:

```
   type AB is new Activation_IF and Value_Retrieval_IF with private;

private

   type AB is new Activation_IF and Value_Retrieval_IF with record
      SA : A;
      SB : B;
   end record;
```

Naturally, we still need to override all the subprograms that are part of the `Activation_IF` and `Value_Retrieval_IF` interfaces. Also, we need to implement the additional `Check` function that was originally only available on system AB. Therefore, we declare these subprograms:

```
overriding procedure Activate (E : in out AB);
overriding function Is_Active (E : AB) return Boolean;
overriding procedure Deactivate (E : in out AB);

overriding function Value (E : AB) return Float;

not overriding function Check (E : AB) return Boolean;
```

91.3.6 Updated source-code

Finally, this is the complete source-code example:

[Ada]

Listing 2606: simple.ads

```
1  package Simple is
2
3     type Activation_IF is interface;
4
5     procedure Activate (E : in out Activation_IF) is abstract;
6     function Is_Active (E : Activation_IF) return Boolean is abstract;
7     procedure Deactivate (E : in out Activation_IF) is abstract;
8
9     type Value_Retrieval_IF is interface;
10
11    function Value (E : Value_Retrieval_IF) return Float is abstract;
12
13    type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF
14      with private;
15
16    overriding procedure Activate (E : in out Sys_Base);
17    overriding function Is_Active (E : Sys_Base) return Boolean;
18    overriding procedure Deactivate (E : in out Sys_Base);
19
20 private
21
22    type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF
```

Deactivating system AB...
System AB is not active
```

91.4 Further Improvements

When analyzing the complete source-code, we see that there are at least two areas that we could still improve.

91.4.1 Dispatching calls

The first issue concerns the implementation of the `Activate` procedure for types derived from `Sys_Base`. For those derived types, we're expecting that the `Activate` procedure of the parent must be called in the implementation of the overriding `Activate` procedure. For example:

```
package body Simple.System_A is

   procedure Activate (E : in out A) is
   begin
      E.Val := (others => 0.0);
      Activate (Sys_Base (E));
   end;
```

If a developer forgets to call that specific `Activate` procedure, however, the system won't work as expected. A better strategy could be the following:

- Declare a new `Activation_Reset` procedure for `Sys_Base` type.
- Make a dispatching call to the `Activation_Reset` procedure in the body of the `Activate` procedure (of the `Sys_Base` type).
- Let the derived types implement their own version of the `Activation_Reset` procedure.

This is a simplified view of the implementation using the points described above:

```
package Simple is

   type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF with
     private;

   not overriding procedure Activation_Reset (E : in out Sys_Base) is abstract;

end Simple;

package body Simple is

   procedure Activate (E : in out Sys_Base) is
   begin
      --  NOTE: calling "E.Activation_Reset" does NOT dispatch!
      --        We need to use the 'Class attribute here --- not using this
      --        attribute is an error that will be caught by the compiler.
      Sys_Base'Class (E).Activation_Reset;

      E.Active := True;
   end Activate;

end Simple;

package Simple.System_A is

   type A is new Sys_Base with private;

private

   type Val_Array is array (Positive range <>) of Float;

   type A is new Sys_Base with record
      Val : Val_Array (1 .. 2);
   end record;

   overriding procedure Activation_Reset (E : in out A);

end Simple.System_A;

package body Simple.System_A is

   procedure Activation_Reset (E : in out A) is
   begin
      E.Val    := (others => 0.0);
   end Activation_Reset;

end Simple.System_A;
```

An important detail is that, in the implementation of `Activate`, we use `Sys_Base'Class` to ensure that the call to `Activation_Reset` will dispatch. If we had just written `E.Activation_Reset` instead, then we would be calling the `Activation_Reset` procedure of `Sys_Base` itself, which is not what we actually want here. The compiler will catch the error if you don't do the conversion to the class-wide type, because it would otherwise be a statically-bound call to an abstract procedure, which is illegal at compile-time.

91.4.2 Dynamic allocation

The next area that we could improve is in the declaration of the system AB. In the previous implementation, we were explicitly describing the two components of that system, namely a component of type A and a component of type B:

```
type AB is new Activation_IF and Value_Retrieval_IF with record
   SA : A;
   SB : B;
end record;
```

Of course, this declaration matches the system requirements that we presented in the beginning. However, we could use strategies that make it easier to incorporate requirement changes later on. For example, we could hide this information about systems A and B by simply declaring an array of components of type **access** Sys_Base'Class and allocate them dynamically in the body of the package. Naturally, this approach might not be suitable for certain platforms. However, the advantage would be that, if we wanted to replace the component of type B by a new component of type C, for example, we wouldn't need to change the interface. This is how the updated declaration could look like:

```
type Sys_Base_Class_Access is access Sys_Base'Class;
type Sys_Base_Array is array (Positive range <>) of Sys_Base_Class_Access;

type AB is limited new Activation_IF and Value_Retrieval_IF with record
   S_Array : Sys_Base_Array (1 .. 2);
end record;
```

Important

Note that we're now using the **limited** keyword in the declaration of type AB. That is necessary because we want to prevent objects of type AB being copied by assignment, which would lead to two objects having the same (dynamically allocated) subsystems A and B internally. This change requires that both Activation_IF and Value_Retrieval_IF are declared limited as well.

The body of Activate could then allocate those components:

```
procedure Activate (E : in out AB) is
begin
   E.S_Array := (new A, new B);
   for S of E.S_Array loop
      S.Activate;
   end loop;
end Activate;
```

And the body of Deactivate could deallocate them:

```
procedure Deactivate (E : in out AB) is
   procedure Free is
     new Ada.Unchecked_Deallocation (Sys_Base'Class, Sys_Base_Class_Access);
begin
   for S of E.S_Array loop
      S.Deactivate;
      Free (S);
   end loop;
end Deactivate;
```

91.4.3 Limited controlled types

Another approach that we could use to implement the dynamic allocation of systems A and B is to declare AB as a limited controlled type — based on the Limited_Controlled type of the Ada.Finalization package.

The Limited_Controlled type includes the following operations:

- `Initialize`, which is called when objects of a type derived from the `Limited_Controlled` type are being created — by declaring an object of the derived type, for example —, and
- `Finalize`, which is called when objects are being destroyed — for example, when an object gets out of scope at the end of a subprogram where it was created.

In this case, we must override those procedures, so we can use them for dynamic memory allocation. This is a simplified view of the updated implementation:

```
package Simple.System_AB is

   type AB is limited new Ada.Finalization.Limited_Controlled and
     Activation_IF and Value_Retrieval_IF with private;

   overriding procedure Initialize (E : in out AB);
   overriding procedure Finalize   (E : in out AB);

end Simple.System_AB;

package body Simple.System_AB is

   overriding procedure Initialize (E : in out AB) is
   begin
      E.S_Array := (new A, new B);
   end Initialize;

   overriding procedure Finalize   (E : in out AB) is
      procedure Free is
        new Ada.Unchecked_Deallocation (Sys_Base'Class, Sys_Base_Class_Access);
   begin
      for S of E.S_Array loop
         Free (S);
      end loop;
   end Finalize;

end Simple.System_AB;
```

91.4.4 Updated source-code

Finally, this is the complete updated source-code example:

[Ada]

Listing 2615: simple.ads

```
1  package Simple is
2
3     type Activation_IF is limited interface;
4
5     procedure Activate (E : in out Activation_IF) is abstract;
6     function Is_Active (E : Activation_IF) return Boolean is abstract;
7     procedure Deactivate (E : in out Activation_IF) is abstract;
8
9     type Value_Retrieval_IF is limited interface;
10
11    function Value (E : Value_Retrieval_IF) return Float is abstract;
12
13    type Sys_Base is abstract new Activation_IF and Value_Retrieval_IF with
14      private;
15
16    overriding procedure Activate (E : in out Sys_Base);
```

(continues on next page)

(continued from previous page)

```

System AB check: PASSED
```

(continues on next page)

(continued from previous page)

```
Deactivating system AB...
System AB is not active
```

Naturally, this is by no means the best possible implementation of system AB. By applying other software design strategies that we haven't covered here, we could most probably think of different ways to use object-oriented programming to improve this implementation. Also, in comparison to the *original implementation* (page 2125), we recognize that the amount of source-code has grown. On the other hand, we now have a system that is factored nicely, and also more extensible.

CHAPTER

NINETYTWO

INTRODUCTION

Ada is a general purpose, high-level programming language designed to support the construction of long-lived, highly-reliable applications. Like all general-purpose languages, only a subset of the full language is appropriate for safety-critical applications because the full language includes facilities that are difficult to analyze and verify to the degree required. This document facilitates identification of subsets appropriate for the highest levels of integrity, including safety-critical applications.

SPARK is a statically verifiable subset of Ada designed specifically for the most critical applications. Ada constructs not amenable to verification are precluded, such as arbitrary use of access types and full tasking. SPARK is also a superset of Ada, with additional contracts for specifying and verifying programs. Many of the guidelines (and more) are implicit in the design of SPARK.

Therefore, this document defines guidelines for the development of high-integrity, safety-critical applications in either the Ada or SPARK programming languages, or both (because the two can be mixed).

92.1 Scope

This document provides guidelines for development decisions, both at the system level and at the unit level, regarding the use of the programming languages Ada and SPARK, as well as related tools, such as static analyzers and unit test generators. It is not concerned with presentation issues such as naming, use of whitespace, or the like.

92.2 Structure

Rather than defining a specific set of rules defining a single subset, this document defines a set of criteria, in the form of guidelines, used by system architects to identify project-specific subsets appropriate to a given project.

The guidelines are separated into related categories, such as storage management, object-oriented programming, concurrency management, and so on. Each guideline is in a separate table, specifying the rule name, a unique identifier, and additional attributes common to each table.

92.3 Enforcement

Detection and enforcement mechanisms are indicated for each guideline. These mechanisms typically consist of the application of a language standard pragma named `Restrictions`, with policy-specific restriction identifiers given as parameters to the pragma [AdaRM2016]. Violations of the given restrictions are then detected and enforced by the Ada compiler.

Alternatively, the AdaCore GNATcheck utility program has rules precisely corresponding to those restriction identifiers, with the same degree of detection and enforcement. For example, the language restriction identifier `No_Unchecked_Deallocation` corresponds to the GNATcheck **+RRestrictions:No_Unchecked_Deallocation** rule.

The advantage of GNATcheck over the compiler is that all generated messages will be collected in the GNATcheck report that can be used as evidence of the level of adherence to the coding standard. In addition, GNATcheck provides a mechanism to deal with accepted exemptions. Note that, when the verification method indicates a GNATcheck rule could be used, the rule will note whether it is part of the standard GNATcheck rule set, or has been provided as-is within the document repository, located here.[468]

In some cases the enforcement mechanism is the SPARK language and analyzer. Many of the guidelines (and more) are implicit in the design of SPARK and are, therefore, automatically enforced.

In some (very) rare cases the enforcement mechanism is manual program inspection, although alternatives (e.g., SPARK) are usually available and recommended. These guidelines are included because they are considered invaluable in this domain.

92.4 About the Rules

Although we refer to them as **rules** in the tables for the sake of brevity, these entries should be considered **guidance** because they require both thought and consideration of project-specific characteristics. For example, in some cases the guidance is to make a selection from among a set of distinct enumerated policies. In other cases a single guideline should be followed but not without some exceptional situations allowing it to be violated. The project lead should consider which guidelines to apply and how best to apply each guideline selected.

92.4.1 Mapping to Other Standards

Many of these rules can also be considered *good* programming practices. As such, many of them can be directly correlated to the *ISO/IEC Guidance to Avoiding Vulnerabilities in Programming Languages* [TR24772]. When a rule addresses one of these vulnerabilities, it is listed in the appropriate subsection.

In addition, MITRE's list of Common Weakness Enumerations [MITRE_CWE] contains many software issues that can be addressed by rules within this standard. Where appropriate, each rule lists the CWE(s) that can be addressed. Note that software CWEs tend to be generalized across all languages, so that many of the weaknesses may be prevented by the language itself. For this reason, the CWEs identified within this document specifically address vulnerabilities that would not be addressed by the Ada language itself (i.e., using the language is not sufficient to prevent the vulnerability).

[468] https://github.com/AdaCore/learn/tree/master/content/courses/Guidelines_for_Safe_and_Secure_Ada_SPARK/rules

CHAPTER

NINETYTHREE

DEFINITIONS

This section contains terms and values used in the definitions of the rules set forth in this chapter.

93.1 Level

Level is the compliance level for the rule. Possible values are:

Mandatory
: Non-compliance with a *Mandatory* recommendation level corresponds to a **high risk** of a software bug. There would need to be a good reason for non-conformity to a mandatory rule and, although it is accepted that exceptional cases may exist, any non-conformance should be accompanied by a clear technical explanation of the exceptional circumstance.

Required
: Non-compliance with a *Required* recommendation level corresponds to a **medium to high risk** of a software bug. Much like a *Mandatory* recommendation, there would need to be a good reason for non-conformity to a required rule. Although it is accepted that more exceptional cases may exist, non-conformance should be accompanied by a clear technical explanation of the exceptional circumstance.

Advisory
: Failure to follow an *Advisory* recommendation does not necessarily result in a software bug; the risk of a direct correlation between non-conformance of an advisory rule and a software bug is low. Non-compliance with an advisory recommendation level does not require a supporting technical explanation, however, as the quality of the code may be impacted, the reason for the non-conformance should be understood.

93.2 Remediation

Remediation indicates the level of difficulty to modify/update code that does not follow this particular rule.

High
: Failure to follow this rule will likely cause an unreasonable amount of modifications/updates to bring the code base into compliance.

Medium
: Failure to follow this rule will likely cause a large amount of modifications/updates to bring the code base into compliance, but those changes may still be cost-effective.

Low
: Failure to follow this rule may cause a small amount of modifications/updates

to bring the code base into compliance, but those changes will be minor compared to the benefit.

N/A

This rule is more of a design decision (as opposed to a coding flaw) and therefore, if the rule is violated, it is done so with a specific purpose.

CHAPTER

NINETYFOUR

DYNAMIC STORAGE MANAGEMENT (DYN)

Goal

Maintainability
✓

Reliability
✓

Portability
Performance
✓

Security
✓

Description
Have a plan for managing dynamic memory allocation and deallocation.

Rules
DYN01, DYN02, DYN03, DYN04, DYN05, DYN06

In Ada, objects are created by being either *declared* or *allocated*. Declared objects may be informally thought of as being created "on the stack" although such details are not specified by the language. *Allocated* objects may be thought of as being allocated "from the heap", which is, again, an informal term. Allocated objects are created by the evaluation of allocators represented by the reserved word `new` and, unlike declared objects, have lifetimes independent of scope.

The terms *static* and *dynamic* tend to be used in place of *declared* and *allocated*, although in traditional storage management terminology all storage allocation in Ada is dynamic. In the following discussion, the term *dynamic allocation* refers to storage that is allocated by allocators. *Static* object allocation refers to objects that are declared. *Deallocation* refers to the reclamation of allocated storage.

Unmanaged dynamic storage allocation and deallocation can lead to storage exhaustion; the required analysis is difficult under those circumstances. Furthermore, access values can establish aliases that complicate verification, and explicit deallocation of dynamic storage can lead to specific errors (e.g., "double free", "use after free") having unpredictable results. As a result, the prevalent approach to storage management in high-integrity systems is to disallow dynamic management techniques completely. [SEI-C] [MISRA2013] [Holzmann2006] [ISO2000]

However, restricted forms of storage management and associated feature usage can support the necessary reliability and analyzability characteristics while retaining sufficient expressive power to justify the analysis expense. The following sections present possible approaches, including the traditional approach in which no dynamic behavior is allowed. Individual projects may then choose which storage management approach best fits their requirements and apply appropriate tailoring, if necessary, to the specific guidelines.

Realization
There is a spectrum of management schemes possible, trading ease of analysis against

increasing expressive power. At one end there is no dynamic memory allocation (and hence, deallocation) allowed, making analysis trivial. At the other end, nearly the full expressive power of the Ada facility is available, but with analyzability partially retained. In the latter, however, the user must create the allocators in such a manner as to ensure proper behavior.

Rule DYN01 is Required, as it avoids problematic features whatever the strategy chosen. Rules DYN02-05 are marked as Advisory, because one of them should be chosen and enforced throughout a given software project.

94.1 Common High Integrity Restrictions (DYN01)

Level → Required

Portability
Performance
Security
✓

Remediation → Low

Verification Method → Compiler restrictions

94.1.1 Reference

Ada Reference Manual: H.4 High Integrity Restrictions[469]

94.1.2 Description

The following restrictions must be in effect:

- `No_Anonymous_Allocators`
- `No_Coextensions`
- `No_Access_Parameter_Allocators`
- `Immediate_Reclamation`

The first three restrictions prevent problematic usage that, for example, may cause unreclaimed (and unreclaimable) storage. The last restriction ensures any storage allocated by the compiler at run-time for representing objects is reclaimed at once. (That restriction does not apply to objects created by allocators in the application.)

[469] http://www.ada-auth.org/standards/12rm/html/RM-H-4.html

94.1.3 Applicable Vulnerability within ISO TR 24772-2

- 4.10 Storage Pool

94.1.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[470]
- **CWE-415 - Double Free**[471]
- **CWE-416 - Use After Free**[472]

94.1.5 Noncompliant Code Example

For No_Anonymous_Allocators:

```
X : access String := new String'("Hello");
...
X := new String'("Hello");
```

For No_Coextensions:

```
type Object (Msg : access String) is ...
Obj : Object (Msg => new String'("Hello"));
```

For No_Access_Parameter_Allocators:

```
procedure P (Formal : access String);
...
P (Formal => new String'("Hello"));
```

94.1.6 Compliant Code Example

For No_Anonymous_Allocators, use a named access type:

```
type String_Reference is access all String;
S : constant String_Reference := new String'("Hello");
X : access String := S;
...
X := S;
```

For No_Coextensions, use a variable of a named access type:

```
type Object (Msg : access String) is ...
type String_Reference is access all String;
S : String_Reference := new String'("Hello");
Obj : Object (Msg => S);
```

For No_Access_Parameter_Allocators, use a variable of a named access type:

```
procedure P (Formal : access String);
type String_Reference is access all String;
S : String_Reference := new String'("Hello");
...
P (Formal => S);
```

[470] https://cwe.mitre.org/data/definitions/401.html
[471] https://cwe.mitre.org/data/definitions/415.html
[472] https://cwe.mitre.org/data/definitions/416.html

94.1.7 Notes

The compiler will detect violations of the first three restrictions. Note that GNATcheck can detect violations in addition to the compiler.

The fourth restriction is a directive for implementation behavior, not subject to source-based violation detection.

94.2 Traditional Static Allocation Policy (DYN02)

Level → Advisory

Category

Safety

Goal

Maintainability
✓

Reliability
✓

Portability
Performance
Security
✓

Remediation → Low

Verification Method → Compiler restrictions

94.2.1 Reference

MISRA C Dir 4.12: "Dynamic memory allocation shall not be used."

94.2.2 Description

The following restrictions must be in effect:

- `No_Allocators`
- `No_Task_Allocators`

Under the traditional approach, no dynamic allocations and no deallocations occur. Only declared objects are used and no access types of any kind appear in the code.

Without allocations there is no issue with deallocation as there would be nothing to deallocate. *Heap* storage exhaustion and fragmentation are clearly prevented although storage may still be exhausted due to insufficient stack size allotments.

In this approach the following constructs are not allowed:

- Allocators
- Access-to-constant access types
- Access-to-variable access types
- User-defined storage pools
- Unchecked Deallocations

94.2.3 Applicable Vulnerability within ISO TR 24772-2

- 4.10 Storage Pool

94.2.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[473]
- **CWE-758 - Reliance on Undefined, Unspecified, or Implementation-Defined Behavior**[474]
- **CWE-771 - Missing Reference to Active Allocated Resource**[475]
- **CWE-1325 - Improperly Controlled Sequential Memory Allocation**[476]

94.2.5 Noncompliant Code Example

Any code using the constructs listed above.

94.2.6 Compliant Code Example

N/A

94.2.7 Notes

The compiler, and/or GNATcheck, will detect violations of the restrictions.

94.3 Access Types Without Allocators Policy (DYN03)

[476] https://cwe.mitre.org/data/definitions/1325.html

94.3.1 Reference

MISRA C Rule 21.3: "The memory allocation and deallocation functions of <stdlib.h> shall not be used."

94.3.2 Description

The following restrictions must be in effect:

- `No_Allocators`
- `No_Dependence => Ada.Unchecked_Deallocation`

In this approach dynamic access values are only created via the attribute `'Access` applied to aliased objects. Allocation and deallocation never occur. As a result, storage exhaustion cannot occur because no *dynamic* allocations occur. Fragmentation cannot occur because there are no deallocations.

In this approach the following constructs are not allowed:

- Allocators
- User-defined storage pools
- Unchecked Deallocations

Aspects should be applied to all access types in this approach, specifying a value of zero for the storage size. Although the restriction `No_Allocators` is present, such clauses may be necessary to prevent any default storage pools from being allocated for the access types, even though the pools would never be used. A direct way to accomplish this is to use **`pragma`** *`Default_Storage_Pool`* with a parameter of **`null`** like so:

```
pragma Default_Storage_Pool (null);
```

The above would also ensure no allocations can occur with access types that have the default pool as their associated storage pool (per Ada Reference Manual: 13.11.3 (6.1/3) Default Storage Pools[477]).

94.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.14 Dangling reference to heap [XYK]

94.3.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[478]
- **CWE-415 - Double Free**[479]
- **CWE-416 - Use After Free**[480]
- **CWE-771 - Missing Reference to Active Allocated Resource**[481]
- **CWE-1325 - Improperly Controlled Sequential Memory Allocation**[482]

[477] http://www.ada-auth.org/standards/12rm/html/RM-13-11-3.html
[478] https://cwe.mitre.org/data/definitions/401.html
[479] https://cwe.mitre.org/data/definitions/415.html
[480] https://cwe.mitre.org/data/definitions/416.html
[481] https://cwe.mitre.org/data/definitions/771.html
[482] https://cwe.mitre.org/data/definitions/1325.html

94.3.5 Noncompliant Code Example

Any code using the constructs listed above.

94.3.6 Compliant Code Example

```
type Descriptor is ...;
type Descriptor_Ref is access all Descriptor;
...
Device : aliased Descriptor;
...
P : Descriptor_Ref := Device'Access;
...
```

94.3.7 Notes

The compiler, and/or GNATcheck, will detect violations of the restrictions.

94.4 Minimal Dynamic Allocation Policy (DYN04)

Level → Advisory

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
Performance
Security

Remediation → Low

Verification Method → Compiler restrictions

94.4.1 Reference

Power of Ten rule 3: "Do not use dynamic memory allocation after initialization."

94.4.2 Description

The following restrictions must be in effect:

- `No_Local_Allocators`
- `No_Dependence => Ada.Unchecked_Deallocation`

In this approach dynamic allocation is only allowed during "start-up" and no later. Deallocations never occur. As a result, storage exhaustion should never occur assuming the initial allotment is sufficient. This assumption is as strong as when using only declared objects on

the "stack" because in that case a sufficient initial storage allotment for the stack must be made.

In this approach the following constructs are not allowed:

- Unchecked Deallocations

Note that some operating systems intended for this domain directly support this policy.

94.4.3 Applicable Vulnerability within ISO TR 24772-2

- 4.10 Storage Pool

94.4.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[483]
- **CWE-415 - Double Free**[484]
- **CWE-416 - Use After Free**[485]
- **CWE-459 - Incomplete Cleanup**[486]
- **CWE-771 - Missing Reference to Active Allocated Resource**[487]
- **CWE-1325 - Improperly Controlled Sequential Memory Allocation**[488]

94.4.5 Noncompliant Code Example

Any code using the constructs listed above.

94.4.6 Compliant Code Example

Code performing dynamic allocations any time prior to an arbitrary point designated as the end of the "startup" interval.

94.4.7 Notes

The compiler, and/or GNATcheck, will detect violations of the restrictions.

94.5 User-Defined Storage Pools Policy (DYN05)

Verification Method → Code inspection

94.5.1 Reference

MISRA C Rule 21.3: "The memory allocation and deallocation functions of <stdlib.h> shall not be used."

94.5.2 Description

There are two issues that make storage utilization analysis difficult:

1. the predictability of the allocation and deallocation implementation, and
2. how access values are used by the application.

The behavior of the underlying implementation is largely undefined and may, for example, consist of calls to the operating system (if present). Application code can manipulate access values beyond the scope of analysis.

Under this policy, the full expressive power of access-to-object types is provided but one of the two areas of analysis difficulty is removed. Specifically, predictability of the allocation and deallocation implementation is achieved via user-defined storage pools. With these storage pools, the implementation of allocation (`new`) and deallocation (instances of `Ada.Unchecked_Deallocation`) is defined by the pool type.

If the pool type is implemented with fixed-size blocks on the stack, allocation and deallocation timing behavior are predictable.

Such an implementation would also be free from fragmentation.

Given an analysis providing the worst-case allocations and deallocations, it would be possible to verify that pool exhaustion does not occur. However, as mentioned such analysis can be quite difficult. A mitigation would be the use of the "owning" access-to-object types provided by SPARK.

In this approach no storage-related constructs are disallowed unless the SPARK subset is applied.

94.5.3 Applicable Vulnerability within ISO TR 24772-2

- 4.10 Storage Pool

94.5.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[489]
- **CWE-415 - Double Free**[490]
- **CWE-416 - Use After Free**[491]

[489] https://cwe.mitre.org/data/definitions/401.html
[490] https://cwe.mitre.org/data/definitions/415.html
[491] https://cwe.mitre.org/data/definitions/416.html

- **CWE-459 - Incomplete Cleanup**[492]

94.5.5 Noncompliant Code Example

Allocation via an access type not tied to a user-defined storage pool.

94.5.6 Compliant Code Example

```
Heap : Sequential_Fixed_Blocks.Storage_Pool
         (Storage_Size => Required_Storage_Size,
          Element_Size => Representable_Obj_Size,
          Alignment    => Representation_Alignment);
type Pointer is access all Unsigned_Longword with
   Storage_Pool => Heap;
Ptr : Pointer;
...
Ptr := new Unsigned_Longword; -- from Heap
```

94.5.7 Notes

Enforcement of this approach can only be provided by manual code review unless SPARK is used.

However, the User-Defined Storage Pools Policy can be enforced statically by specifying `Default_Storage_Pool (null)`. This essentially requires all access types to have a specified storage pool if any allocators are used with the access type.

94.6 Statically Determine Maximum Stack Requirements (DYN06)

Verification Method → Static analysis tools

[492] https://cwe.mitre.org/data/definitions/459.html

94.6.1 Reference

N/A

94.6.2 Description

Each Ada application task has a stack, as does the "environment task" that elaborates library packages and calls the main subprogram. A tool to statically determine the maximum storage required for these stacks must be used, per task.

This guideline concerns another kind of dynamic memory utilization. The previous guidelines concerned the management of storage commonly referred to as the "heap." This guideline concerns the storage commonly referred to as the "stack." (Neither term is defined by the language, but both are commonly recognized and are artifacts of the underlying run-time library or operating system implementation.)

94.6.3 Applicable Vulnerability within ISO TR 24772-2

- 4.10 Storage Pool

94.6.4 Applicable Common Weakness Enumeration

- **CWE-770 - Allocation of Resources Without Limits or Throttling**[493]
- **CWE-789 - Uncontrolled Memory Allocation**[494]

94.6.5 Noncompliant Code Example

N/A

94.6.6 Compliant Code Example

N/A

94.6.7 Notes

The GNATstack[495] tool can statically determine the maximum requirements per task.

Verification Method → Code inspection

95.1.1 Reference

N/A

95.1.2 Description

Never deallocate the storage designated by a given access value more than once.

95.1.3 Applicable Vulnerability within ISO TR 24772-2

- 6.39 Memory leak and heap fragmentation [XYL]

95.1.4 Applicable Common Weakness Enumeration

- **CWE-415 - Double Free**[496]
- **CWE-416 - Use After Free**[497]

95.1.5 Noncompliant Code Example

```
   type String_Reference is access all String;
   procedure Free is new Ada.Unchecked_Deallocation
      (Object => String, Name => String_Reference);
   S : String_Reference := new String'("Hello");
   Y : String_Reference;
begin
   Y := S;
   Free (S);
   Free (Y);
```

95.1.6 Compliant Code Example

Remove the call to `Free (Y)`.

95.1.7 Notes

Enforcement of this rule can be provided by manual code review, unless deallocation is forbidden via `No_Unchecked_Deallocation` or SPARK is used, as ownership analysis in SPARK detects such cases. Note that storage utilization analysis tools such as Valgrind can usually find this sort of error. In addition, a GNAT-defined storage pool is available to help debug such errors.

Performance
Security
✓

Remediation → High

Verification Method → Code inspection

95.3.1 Reference

N/A

95.3.2 Description

When deallocating, ensure that the pool to which the storage will be returned is the same pool from which it was allocated. Execution is erroneous otherwise, meaning anything can happen (Ada Reference Manual: 13.11.2 (16) Unchecked Storage Deallocation[499]).

Each access type has an associated storage pool, either implicitly by default, or explicitly with a storage pool specified by the programmer. The implicit default pool might not be the same pool used for another access type, even an access type designating the same subtype.

95.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.39 Memory leak and heap fragmentation [XYL]

95.3.4 Applicable Common Weakness Enumeration

- **CWE-401 - Missing Release of Memory after Effective Lifetime**[500]

95.3.5 Noncompliant Code Example

[499] http://www.ada-auth.org/standards/12rm/html/RM-13-11-2.html
[500] https://cwe.mitre.org/data/definitions/401.html

```
   type Pointer1 is access all Integer;
   type Pointer2 is access all Integer;
   P1 : Pointer1;
   P2 : Pointer2;
   procedure Free is new Ada.Unchecked_Deallocation
      (Object => Integer, Name => Pointer2);
begin
   P1 := new Integer;
   P2 := Pointer2 (P1);
   Call_Something ( P2.all );
   ...
   Free (P2);
```

In the above, P1.**all** was allocated from Pointer1'Storage_Pool, but, via the type conversion, the code above is attempting to return it to Pointer2'Storage_Pool, which may be a different pool.

95.3.6 Compliant Code Example

```
   type Pointer1 is access all Integer;
   type Pointer2 is access all Integer;
   P1 : Pointer1;
   P2 : Pointer2;
   procedure Free is new Ada.Unchecked_Deallocation
      (Object => Integer, Name => Pointer1);
begin
   P1 := new Integer;
   P2 := Pointer2 (P1);
   Call_Something ( P2.all );
   ...
   Free (P1);
```

95.3.7 Notes

Enforcement of this rule can only be provided by manual code review, unless deallocation is forbidden via No_Unchecked_Deallocation.

NINETYSIX

CONCURRENCY (CON)

Goal

Maintainability

✓

Reliability

✓

Portability

✓

Performance

✓

Security

Description

Have a plan for managing the use of concurrency in high-integrity applications having real-time requirements.

Rules

CON01, CON02, CON03

The canonical approach to applications having multiple periodic and aperiodic activities is to map those activities onto independent tasks, i.e., threads of control. The advantages for the application are both a matter of software engineering and also ease of implementation. For example, when the different periods are not harmonics of one another, the fact that each task executes independently means that the differences are trivially represented. In contrast, such periods are not easily implemented in a cyclic scheduler, which, by definition, involves only one (implicit) thread of control with one frame rate.

High integrity applications are subject to a number of stringent analyses, including, for example, safety analyses and certification against rigorous industry standards. In addition, high integrity applications with real-time requirements must undergo timing analysis because they must be shown to meet deadlines prior to deployment — failure to meet hard deadlines is unacceptable in this domain.

These analyses are applied both to the application and to the implementation of the underlying run-time library. However, analysis of the complete set of general Ada tasking features is not tractable, neither technically nor in terms of cost. A subset of the language is required.

The Ravenscar profile [AdaRM2016] is a subset of the Ada concurrency facilities that supports determinism, schedulability analysis, constrained memory utilization, and certification to the highest integrity levels. Four distinct application domains are specifically intended:

- Hard real-time applications requiring predictability;
- Safety-critical systems requiring formal, stringent certification;
- High-integrity applications requiring formal static analysis and verification;

- Embedded applications requiring both a small memory footprint and low execution overhead.

Those tasking constructs that preclude analysis at the source level or analysis of the tasking portion of the underlying run-time library are disallowed.

The Ravenscar profile is necessarily strict in terms of what it removes so that it can support the stringent analyses, such as safety analysis, that go beyond the timing analysis required for real-time applications. In addition, the strict subset facilitates that timing analysis in the first place.

However, not all high-integrity applications are amenable to expression in the Ravenscar profile subset. The Jorvik profile [AdaRM2020] is an alternative subset of the Ada concurrency facilities. It is based directly on the Ravenscar profile but removes selected restrictions in order to increase expressive power, while retaining analyzability and performance. As a result, typical idioms for protected objects can be used, for example, and relative delays statements are allowed. Timing analysis is still possible but slightly more complicated, and the underlying run-time library is slightly larger and more complex.

When the most stringent analyses are required and the tightest timing is involved, use the Ravenscar profile. When a slight increase in complexity is tolerable, i.e., in those cases not undergoing all of these stringent analyses, consider using the Jorvik profile.

96.1 Use the Ravenscar Profile (CON01)

96.1.1 Reference

Ada Reference Manual: D.13 The Ravenscar and Jorvik Profiles[501]

[501] http://www.ada-auth.org/standards/12rm/html/RM-D-13.html

96.1.2 Description

The following profile must be in effect:

```
pragma Profile (Ravenscar);
```

The profile is equivalent to the following set of pragmas:

```
pragma Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
pragma Restrictions (
        No_Abort_Statements,
        No_Dynamic_Attachment,
        No_Dynamic_CPU_Assignment,
        No_Dynamic_Priorities,
        No_Implicit_Heap_Allocations,
        No_Local_Protected_Objects,
        No_Local_Timing_Events,
        No_Protected_Type_Allocators,
        No_Relative_Delay,
        No_Requeue_Statements,
        No_Select_Statements,
        No_Specific_Termination_Handlers,
        No_Task_Allocators,
        No_Task_Hierarchy,
        No_Task_Termination,
        Simple_Barriers,
        Max_Entry_Queue_Length => 1,
        Max_Protected_Entries => 1,
        Max_Task_Entries => 0,
        No_Dependence => Ada.Asynchronous_Task_Control,
        No_Dependence => Ada.Calendar,
        No_Dependence => Ada.Execution_Time.Group_Budgets,
        No_Dependence => Ada.Execution_Time.Timers,
        No_Dependence => Ada.Synchronous_Barriers,
        No_Dependence => Ada.Task_Attributes,
        No_Dependence => System.Multiprocessors.Dispatching_Domains);
```

96.1.3 Applicable Vulnerability within ISO TR 24772-2

- 6.59 Concurrency - Activation [GGA]
- 6.60 Concurrency - Directed termination [CGT]
- 6.61 Concurrent data access [CGX]
- 6.62 Concurrency - Premature termination [CGS]
- 6.63 Lock protocol errors [CGM]

96.1.4 Applicable Common Weakness Enumeration

- **CWE-362 - Concurrent Execution using Shared Resource with Improper Synchronization**[502]
- **CWE-366 - Race Condition within a Thread**[503]
- **CWE-367 - Time-of-check Time-of-use (TOCTOU) Race Condition**[504]

[502] https://cwe.mitre.org/data/definitions/362.html
[503] https://cwe.mitre.org/data/definitions/366.html
[504] https://cwe.mitre.org/data/definitions/367.html

96.1.5 Noncompliant Code Example

Any code disallowed by the profile. Remediation is **high** because use of the facilities outside the subset can be difficult to retrofit into compliance.

```
task body Task_T is
begin
   loop
      -- Error: No_Relative_Delay
      delay 1.0;
      Put_Line ("Hello World");
   end loop;
end Task_T;
```

96.1.6 Compliant Code Example

```
task body Task_T is
   Period     : constant Time_Span := Milliseconds (10);
   Activation : Time               := Clock;
begin
   loop
      delay until Activation;
      Put_Line ("Hello World");
      Activation := Activation + Period;
   end loop;
end Task_T;
```

96.1.7 Notes

The Ada builder will detect violations if the programmer specifies this profile or corresponding pragmas. GNATcheck also can detect violations of profile restrictions.

96.2 Use the Jorvik Profile (CON02)

Verification Method → GNATcheck rule: `uses_profile:jorvik` (supplied with document)

Mutually Exclusive → CON01

96.2.1 Reference

Ada Reference Manual: D.13 The Ravenscar and Jorvik Profiles[505]

96.2.2 Description

The following profile must be in effect:

```
pragma Profile (Jorvik);
```

The profile is equivalent to the following set of pragmas:

```
pragma Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
pragma Restrictions (
           No_Abort_Statements,
           No_Dynamic_Attachment,
           No_Dynamic_CPU_Assignment,
           No_Dynamic_Priorities,
           No_Local_Protected_Objects,
           No_Local_Timing_Events,
           No_Protected_Type_Allocators,
           No_Requeue_Statements,
           No_Select_Statements,
           No_Specific_Termination_Handlers,
           No_Task_Allocators,
           No_Task_Hierarchy,
           No_Task_Termination,
           Pure_Barriers,
           Max_Task_Entries => 0,
           No_Dependence => Ada.Asynchronous_Task_Control,
           No_Dependence => Ada.Execution_Time.Group_Budgets,
           No_Dependence => Ada.Execution_Time.Timers,
           No_Dependence => Ada.Task_Attributes,
           No_Dependence => System.Multiprocessors.Dispatching_Domains);
```

The following restrictions are part of the Ravenscar profile but **not** part of the Jorvik profile.

```
No_Implicit_Heap_Allocations
No_Relative_Delay
Max_Entry_Queue_Length => 1
Max_Protected_Entries => 1
No_Dependence => Ada.Calendar
No_Dependence => Ada.Synchronous_Barriers
```

Jorvik also replaces restriction `Simple_Barriers` with `Pure_Barriers` (a weaker requirement than the restriction `Simple_Barriers`).

[505] http://www.ada-auth.org/standards/12rm/html/RM-D-13.html

96.2.3 Applicable Vulnerability within ISO TR 24772-2

- 6.59 Concurrency - Activation [GGA]
- 6.60 Concurrency - Directed termination [CGT]
- 6.61 Concurrent data access [CGX]
- 6.62 Concurrency - Premature termination [CGS]
- 6.63 Lock protocol errors [CGM]

96.2.4 Applicable Common Weakness Enumeration

- **CWE-362 - Concurrent Execution using Shared Resource with Improper Synchronization**[506]
- **CWE-366 - Race Condition within a Thread**[507]
- **CWE-367 - Time-of-check Time-of-use (TOCTOU) Race Condition**[508]

96.2.5 Noncompliant Code Example

Any code disallowed by the profile. Remediation is **high** because use of the facilities outside the subset can be difficult to retrofit into compliance.

```
task body Task_T is
begin
   -- Error: Max_Task_Entries => 0
   accept Entry_Point do
      Put_Line ("Hello World");
   end Entry_Point;
   loop
      delay 1.0;
      Put_Line ("Ping");
   end loop;
end Task_T;
```

96.2.6 Compliant Code Example

```
task body Task_T is
begin
   delay 1.0;
   Put_Line ("Hello World");
   loop
      delay 1.0;
      Put_Line ("Ping");
   end loop;
end Task_T;
```

96.2.7 Notes

The Ada builder will detect violations. GNATcheck can also detect violations.

[506] https://cwe.mitre.org/data/definitions/362.html
[507] https://cwe.mitre.org/data/definitions/366.html

96.3 Avoid Shared Variables for Inter-task Communication (CON03)

Level → Advisory

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
✓

Performance
✓

Security

Remediation → High

Verification Method → GNATcheck rule: `Volatile_Objects_Without_Address_Clauses` (builtin rule)

96.3.1 Reference

Ada Reference Manual: D.13 The Ravenscar Profile[509]

96.3.2 Description

Although the Ravenscar and Jorvik profiles allow the use of shared variables for inter-task communication, such use is less robust and less reliable than encapsulating shared variables within protected objects.

96.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.56 Undefined behaviour [EWF]

96.3.4 Applicable Common Weakness Enumeration

- **CWE-567 - Unsynchronized Access to Shared Data in a Multithreaded Context**[510]
- **CWE-667 - Improper Locking**[511]

[509] http://www.ada-auth.org/standards/12rm/html/RM-D-13.html
[510] https://cwe.mitre.org/data/definitions/567.html
[511] https://cwe.mitre.org/data/definitions/667.html

96.3.5 Noncompliant Code Example

```
Global_Object : Integer
  with Volatile;
function Get return Integer is (Global_Object);
```

Note that variables marked as `Atomic` are also `Volatile`, per the Ada Reference Manual: C.6 (8/3) Shared Variable Control[512]

96.3.6 Compliant Code Example

When assigned to a memory address, a `Volatile` variable can be used to interact with a memory-mapped device, among other similar usages.

```
Global_Object : Integer
  with Volatile,
       Address => To_Address (16#1234_5678#);
function Get return Integer is (Global_Object);
```

96.3.7 Notes

In addition to GNATcheck, SPARK and CodePeer can also detect conflicting access to unprotected variables.

[512] http://www.ada-auth.org/standards/12rm/html/RM-C-6.html

Performance
Security

Remediation → Low

Verification Method → GNATcheck rule: `OTHERS_In_CASE_Statements` (builtin rule)

97.1.1 Reference

[SEI-C] MSC01-C

97.1.2 Description

Case statement alternatives and case-expressions must not include use of the **`others`** discrete choice option. This rule prevents accidental coverage of a choice added after the initial case statement is written, when an explicit handler was intended for the addition.

Note that this is opposite to typical C guidelines such as [SEI-C] MSC01-C. The reason is that in C, the **`default`** alternative plays the role of defensive code to mitigate the switch statement's non-exhaustivity. In Ada, the **`case`** construct is exhaustive: the compiler statically verifies that for every possible value of the **`case`** expression there is a branch alternative, and there is also a dynamic check against invalid values which serves as implicit defensive code. As a result, Ada's **`others`** alternative doesn't play C's defensive code role and therefore a stronger guideline can be adopted.

97.1.3 Applicable Vulnerability within ISO TR 24772-2

- 6.27 Switch statements and static analysis [CLL]

97.1.4 Applicable Common Weakness Enumeration

- **CWE-478 - Missing Default Case in Multiple Condition Expression**[513]

97.1.5 Noncompliant Code Example

```
case Digit_T (C) is
   when '0' | '9' =>
      C := Character'succ (C);
   when others =>
      C := Character'pred (C);
end case;
```

97.1.6 Compliant Code Example

```
case Digit_T (C) is
   when '0' | '9' =>
      C := Character'succ (C);
   when '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' =>
      C := Character'pred (C);
end case;
```

97.1.7 Notes

[513] https://cwe.mitre.org/data/definitions/478.html

97.2 No Enumeration Ranges in Case Constructs (RPP02)

Level → Required

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
✓

Performance
Security

Remediation → Low

Verification Method → GNATcheck rule: `Enumeration_Ranges_In_CASE_Statements` (builtin rule)

97.2.1 Reference

Similar to RPP01

97.2.2 Description

A range of enumeration literals must not be used as a choice in a **case** statement or a **case** expression. This includes explicit ranges (`A .. B`), subtypes, and the `'Range` attribute. Much like the use of **others** in **case** statement alternatives, the use of ranges makes it possible for a new enumeration value to be added but not handled with a specific alternative, when a specific alternative was intended.

97.2.3 Applicable Vulnerability within ISO TR 24772-2

- 6.5 Enumerator issues [CCB]

97.2.4 Applicable Common Weakness Enumeration

N/A

97.2.5 Noncompliant Code Example

```
case Digit_T (C) is
   when '0' | '9' =>
      C := Character'Succ (C);
   when '1' .. '8' =>
      C := Character'Pred (C);
end case;
```

97.2.6 Compliant Code Example

```
case Digit_T (C) is
   when '0' | '9' =>
      C := Character'Succ (C);
   when '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' =>
      C := Character'Pred (C);
end case;
```

97.2.7 Notes

N/A

97.3 Limited Use of "others" in Aggregates (RPP03)

Level → Advisory

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
✓

Performance
Security

Remediation → Low

Verification Method → GNATcheck rule: `OTHERS_In_Aggregates` (builtin rule)

97.3.1 Reference

Similar to RPP01

97.3.2 Description

Do not use an **others** choice in an extension aggregate. In **record** and **array** aggregates, do not use an **others** choice unless it is used either to refer to all components, or to all but one component.

This guideline prevents accidental provision of a general value for a **record** component or **array** component, when a specific value was intended. This possibility includes the case in which new components are added to an existing composite type.

97.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.5 Enumerator issues [CCB]
- 6.27 Switch statements and static analysis [CLL]

97.3.4 Applicable Common Weakness Enumeration

- **CWE-478 - Missing Default Case in Multiple Condition Expression**[514]

97.3.5 Noncompliant Code Example

```
type Record_T is record
   Field1 : Integer   := 1;
   Field2 : Boolean   := False;
   Field3 : Character := ' ';
end record;
type Array_T is array (Character) of Boolean;
Rec : Record_T := (Field1 => 1,
                   Field3 => '2',
                   others => <>);
Arr : Array_T := ('0' .. '9' => True,
                  others     => False);
```

97.3.6 Compliant Code Example

```
type Record_T is record
   Field1 : Integer   := 1;
   Field2 : Boolean   := False;
   Field3 : Character := ' ';
end record;
type Array_T is array (Character) of Boolean;
Rec : Record_T := (Field1 => 1,
                   others => <>);
Arr : Array_T := (others => False);
```

97.3.7 Notes

97.4 No Unassigned Mode-Out Procedure Parameters (RPP04)

Level → Required

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

[514] https://cwe.mitre.org/data/definitions/478.html

Reliability
✓

Portability
✓

Performance
Security

Remediation → High

Verification Method → GNATcheck rule: `Unassigned_OUT_Parameters` (builtin rule)

97.4.1 Reference

MISRA C Rule 9.1: "The value of an object with automatic storage duration shall not be read before it has been set."

97.4.2 Description

For any procedure, all formal parameters of mode **out** must be assigned a value if the procedure exits normally. This rule ensures that, upon a normal return, the corresponding actual parameter has a defined value. Ensuring a defined value is especially important for scalar parameters because they are passed by value, such that some value is copied out to the actual. These undefined values can be especially difficult to locate because evaluation of the actual parameter's value might not occur immediately after the call returns.

97.4.3 Applicable Vulnerability within ISO TR 24772-2

- 6.32 Passing parameters and return values [CSJ]

97.4.4 Applicable Common Weakness Enumeration

- **CWE-457 - Use of Uninitialized Variable**[515]

97.4.5 Noncompliant Code Example

```
for Value_T use
  (Alpha   => 2#1#,
   Baker   => 2#10#,
   Charlie => 2#100#,
   Dog     => 2#1000#,
   Invalid => 2#1111#);

procedure Noncompliant (Register  :     Character;
                        Registera : out Value_T;
                        Registerb : out Value_T) is
begin
   if Register = 'A' then
      Registera := Alpha;
   end if;
end Noncompliant;
```

In the above example, some value is copied back for an output parameter as specified by `Register`. The other parameter is not assigned, and on return the value copied to the actual parameter may not be a valid representation for a value of the type. (We give the enumeration values a non-standard representation for the sake of illustration, i.e., to make it more likely that the undefined value is not valid.)

[515] https://cwe.mitre.org/data/definitions/457.html

97.4.6 Compliant Code Example

```
procedure Compliant (Register  :     Character;
                     Registera : out Value_T;
                     Registerb : out Value_T) is
begin
   Registera := Invalid;
   Registerb := Invalid;
   if Register = 'A' then
      Registera := Alpha;
   end if;
end Compliant;
```

97.4.7 Notes

The GNATcheck rule specified above only detects a trivial case of an unassigned variable and doesn't provide a guarantee that there is no uninitialized access. It is not a replacement for a rigorous check for uninitialized access provided by advanced static analysis tools such as SPARK and CodePeer.

Note that the GNATcheck rule does not check function parameters (as of Ada 2012 functions can have **out** parameters). As a result, the better choice is either SPARK or CodePeer.

97.5 No Use of "others" in Exception Handlers (RPP05)

Level → Required

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
✓

Performance
Security

Remediation → Low

Verification Method → GNATcheck rule: `OTHERS_In_Exception_Handlers` (builtin rule)

97.5.1 Reference

N/A

97.5.2 Description

Much like the situation with **others** in **case** statements and **case** expressions, the use of **others** in exception handlers makes it possible to omit an intended specific handler for an exception, especially a new exception added to an existing set of handlers. As a result, a subprogram could return normally without having applied any recovery for the specific exception occurrence, which is likely a coding error.

97.5.3 Applicable Vulnerability within ISO TR 24772-2

N/A

97.5.4 Applicable Common Weakness Enumeration

- **CWE-396 - Declaration of Catch for Generic Exception**[516]

97.5.5 Noncompliant Code Example

```
procedure Noncompliant (X : in out Integer) is
begin
   X := X * X;
exception
   when others =>
      X := -1;
end Noncompliant;
```

97.5.6 Compliant Code Example

```
procedure Compliant (X : in out Integer) is
begin
   X := X * X;
exception
   when Constraint_Error =>
      X := -1;
end Compliant;
```

97.5.7 Notes

ISO TR 24772-2: 6.50.2 slightly contradicts this when applying exception handlers around calls to library routines:

- Put appropriate exception handlers in all routines that call library routines, including the catch-all exception handler **when others** =>
- Put appropriate exception handlers in all routines that are called by library routines, including the catch-all exception handler **when others** =>

ISO TR 24772-2 also recommends "All tasks should contain an exception handler at the outer level to prevent silent termination due to unhandled exceptions."

97.6 Avoid Function Side-Effects (RPP06)

Level → Advisory

Category

Verification Method → Code inspection

97.6.1 Reference

MISRA C Rule 13.2: "The value of an expression and its persistent side effects shall be the same under all permitted evaluation orders."

97.6.2 Description

Functions cannot update an actual parameter or global variable.

A side effect occurs when evaluation of an expression updates an object. This rule applies to function calls, a specific form of expression.

Side effects enable one form of parameter aliasing (see below) and evaluation order dependencies. In general they are a potential point of confusion because the reader expects only a computation of a value.

There are useful idioms based on functions with side effects. Indeed, a random number generator expressed as a function must use side effects to update the seed value. So-called "memo" functions are another example, in which the function tracks the number of times it is called. Therefore, exceptions to this rule are anticipated but should only be allowed on a per-instance basis after careful analysis.

97.6.3 Applicable Vulnerability within ISO TR 24772-2

- 6.24 Side-effects and order of evaluation [SAM]

97.6.4 Applicable Common Weakness Enumeration

N/A

97.6.5 Noncompliant Code Example

```
Call_Count : Integer := 0;
function F return Boolean is
   Result : Boolean;
begin
   ...
```

(continues on next page)

(continued from previous page)

```
   Call_Count := Call_Count + 1;
   return Result;
end F;
```

97.6.6 Compliant Code Example

Remove the update to `Call_Count`, or change the function into a procedure with a parameter for `Call_Count`.

97.6.7 Notes

Violations are detected by SPARK as part of a rule disallowing side effects on expression evaluation.

97.7 Functions Only Have Mode "in" (RPP07)

Level → Required

Category

Safety
✓

Cyber
✓

Goal

Maintainability
✓

Reliability
✓

Portability
✓

Performance
Security

Remediation → Low

Verification Method → GNATcheck rule: `function_out_parameters` (supplied with document)

97.7.1 Reference

N/A

97.7.2 Description

Functions must have only mode **in**.

As of Ada 2012, functions are allowed to have the same modes as procedures. However, this can lead to side effects and aliasing.

This rule disallows all modes except mode **in** for functions.

97.7.3 Applicable Vulnerability within ISO TR 24772-2

- 6.24 Side-effects and order of evaluation [SAM]

97.7.4 Applicable Common Weakness Enumeration

N/A

97.7.5 Noncompliant Code Example

```
function Noncompliant (Value : in out Integer) return Integer is
begin
   if Value < Integer'last then
      Value := Value + 1;
   end if;
   return Value;
end Noncompliant;
```

97.7.6 Compliant Code Example

```
function Compliant (Value : Integer) return Integer is
begin
   return Value + 1;
end Compliant;
```

OR

```
procedure Compliant (Value : in out Integer) is
begin
   if Value < Integer'last then
      Value := Value + 1;
   end if;
end Compliant;
```

97.7.7 Notes

Violations are detected by SPARK.

97.8.1 Reference

Ada Reference Manual: 6.2 Formal Parameter Modes[517]

SPARK Reference Manual: Anti-Aliasing[518]

97.8.2 Description

In software, an alias is a name which refers to the same object as another name. In some cases, it is an error in Ada to reference an object through a name while updating it through another name in the same subprogram. Most of these cases cannot be detected by a compiler. Even when not an error, the presence of aliasing makes it more difficult to understand the code for both humans and analysis tools, and thus it may lead to errors being introduced during maintenance.

This rule is meant to detect problematic cases of aliasing that are introduced through the actual parameters and between actual parameters and global variables in a subprogram call. It is a simplified version of the SPARK rule for anti-aliasing defined in SPARK Reference Manual, section 6.4.2: Anti-Aliasing[519].

A formal parameter is said to be immutable when the subprogram cannot modify its value or modify the value of an object by dereferencing a part of the parameter of access type (at any depth in the case of SPARK). In Ada and SPARK, this corresponds to either an anonymous access-to-constant parameter or a parameter of mode `in` and not of an access type. Otherwise, the formal parameter is said to be mutable.

A procedure call shall not pass two actual parameters which potentially introduce aliasing via parameter passing unless either:

- both of the corresponding formal parameters are immutable; or
- at least one of the corresponding formal parameters is immutable and is of a by-copy type that is not an access type.

If an actual parameter in a procedure call and a global variable referenced by the called procedure potentially introduce aliasing via parameter passing, then:

- the corresponding formal parameter shall be immutable; and
- if the global variable is written in the subprogram, then the corresponding formal parameter shall be of a by-copy type that is not an access type.

Where one of the rules above prohibits the occurrence of an object or any of its subcomponents as an actual parameter, the following constructs are also prohibited in this context:

- A type conversion whose operand is a prohibited construct;
- A call to an instance of `Unchecked_Conversion` whose operand is a prohibited construct;
- A qualified expression whose operand is a prohibited construct;
- A prohibited construct enclosed in parentheses.

97.8.3 Applicable Vulnerability within ISO TR 24772-2

- 6.32 Passing parameters and return values [CSJ]

97.8.4 Applicable Common Weakness Enumeration

N/A

97.8.5 Noncompliant Code Example

```
   type R is record
     Data : Integer := 0;
   end record;

   procedure Detect_Aliasing (Val_1 : in out R;
                              Val_2 : in R)
   is
   begin
      null;
   end Detect_Aliasing;

   Obj : R;

begin
   Detect_Aliasing (Obj, Obj);
```

97.8.6 Compliant Code Example

Do not pass `Obj` as the actual parameter to both formal parameters.

97.8.7 Notes

All violations are detected by SPARK. The GNAT compiler switch `-gnateA[1]` enables detection of some cases, but not all.

97.9 Use Precondition and Postcondition Contracts (RPP09)

Level → Advisory

Category

Verification Method → Code inspection

97.9.1 Reference

Power of Ten rule 5: "The assertion density of the code should average to a minimum of two assertions per function."

97.9.2 Description

Subprograms should declare `Pre` and/or `Post` contracts. Developers should consider specifying the Global contract as well, when the default does not apply.

Subprogram contracts complete the Ada notion of a specification, enabling clients to know what the subprogram does without having to know how it is implemented.

Preconditions define those logical (Boolean) conditions required for the body to be able to provide the specified behavior. As such, they are obligations on the callers. These conditions are checked at run-time in Ada, prior to each call, and verified statically in SPARK.

Postconditions define those logical (Boolean) conditions that will hold after the call returns normally. As such, they express obligations on the implementer, i.e., the subprogram body. The implementation must be such that the postcondition holds, either at run-time for Ada, or statically in SPARK.

Not all subprograms will have both a precondition and a postcondition, some will have neither.

The `Global` contract specifies interactions with those objects not local to the corresponding subprogram body. As such, they help complete the specification because, otherwise, one would need to examine the body of the subprogram itself and all those it calls, directly or indirectly, to know whether any global objects were accessed.

97.9.3 Applicable Vulnerability within ISO TR 24772-2

- 6.42 Violations of the Liskov substitution principle or the contract model [BLP]

97.9.4 Applicable Common Weakness Enumeration

- **CWE-754 - Improper Check for Unusual or Exceptional Conditions**[520]

97.9.5 Noncompliant Code Example

```
type Stack is private;
procedure Push (This : in out Stack;  Item : Element);
```

97.9.6 Compliant Code Example

```
type Stack is private;
procedure Push (This : in out Stack;  Item : Element) with
   Pre  => not Full (This),
```

(continues on next page)

[520] https://cwe.mitre.org/data/definitions/754.html

(continued from previous page)

```
   Post => not Empty (This)
           and Top_Element (This) = Item
           and Extent (This) = Extent (This)'Old + 1
           and Unchanged (This'Old, Within => This),
   Global => null;
```

97.9.7 Notes

This rule must be enforced by manual inspection.

Moreover, the program must be compiled with enabled assertions (GNAT `-gnata` switch) to ensure that the contracts are executed, or a sound static analysis tool such as CodePeer or SPARK toolset should be used to prove that the contracts are always true.

97.10 Do Not Re-Verify Preconditions in Subprogram Bodies (RPP10)

Performance
Security

Remediation → Low

Verification Method → Compiler restrictions

97.11.1 Reference

MISRA C Rule 17.7: "The value returned by a function having non-void return type shall be used," and

Directive 4.7: "If a function returns error information, that error information shall be tested."

97.11.2 Description

In Ada and SPARK, it is not possible to ignore the object returned by a function call. The call must be treated as a value, otherwise the compiler will reject the call. For example, the value must be assigned to a variable, or passed as the actual parameter to a formal parameter of another call, and so on.

However, that does not mean that the value is actually used to compute some further results. Although almost certainly a programming error, one could call a function, assign the result to a variable (or constant), and then not use that variable further.

Note that functions will not have side-effects (due to RPP06) so it is only the returned value that is of interest here.

97.11.3 Applicable Vulnerability within ISO TR 24772-2

- 6.47 Inter-language calling [DJS]

97.11.4 Applicable Common Weakness Enumeration

- **CWE-252 - Unchecked Return Value**[521]
- **CWE-563 - Assignment to Variable without Use**[522]

97.11.5 Noncompliant Code Example

N/A

97.11.6 Compliant Code Example

N/A

97.11.7 Notes

The GNAT compiler warning switch `-gnatwu` (or the more general `-gnatwa` warnings switch) will cause the compiler to detect variables assigned but not read. CodePeer will detect these unused variables as well. SPARK goes further by checking that all computations contribute all the way to subprogram outputs.

Verification Method → GNATcheck rule: `Recursive_Subprograms` (builtin rule)

97.12.1 Reference

MISRA C Rule 17.2: "Functions shall not call themselves, either directly or indirectly."

97.12.2 Description

No subprogram shall be invoked, directly or indirectly, as part of its own execution.

In addition to making static analysis more complex, recursive calls make static stack usage analysis extremely difficult, requiring, for example, manual supply of call limits.

97.12.3 Applicable Vulnerability within ISO TR 24772-2

- 6.35 Recursion [GDL]

97.12.4 Applicable Common Weakness Enumeration

- **CWE-674 - Uncontrolled Recursion**[523]

97.12.5 Noncompliant Code Example

```
function Noncompliant (N : Positive) return Positive is
begin
   if N = 1 then
      return 1;
   else
      return N * Noncompliant (N - 1);  -- could overflow
   end if;
end Noncompliant;
```

[523] https://cwe.mitre.org/data/definitions/674.html

97.12.6 Compliant Code Example

```
function Compliant (N : Positive) return Positive is
   Result : Positive := 1;
begin
   for K in 2 .. N loop
      Result := Result * K;  -- could overflow
   end loop;
   return Result;
end Compliant;
```

97.12.7 Notes

The compiler will detect violations with the restriction `No_Recursion` in place. Note this is a dynamic check.

The GNATcheck rule specified above is a static check, subject to the limitations described in GNATcheck Reference Manual: Recursive Subprograms[524].

97.13 No Reuse of Standard Typemarks (RPP13)

Verification Method → GNATcheck rule: `Numeric_Literals` (builtin rule)

[525] https://cwe.mitre.org/data/definitions/843.html

97.14.1 Reference

N/A

97.14.2 Description

Extensive use of literals in a program can lead to two problems. First, the meaning of the literal is often obscured or unclear from the context. Second, changing a frequently used literal requires searching the entire program source for that literal and distinguishing the uses that must be modified from those that should remain unmodified.

Avoid these problems by declaring objects with meaningfully named constants, setting their values to the desired literals, and referencing the constants instead of the literals throughout the program. This approach clearly indicates the meaning or intended use of each literal. Furthermore, should the constant require modification, the change is limited to the declaration; searching the code is unnecessary.

Some literals can be replaced with attribute values. For example, when iterating over an array, it is better to use `Array_Object'First .. Array_Object'Last` than using `1 .. Array_Object'Length`.

97.14.3 Applicable Vulnerability within ISO TR 24772-2

Description
Have a plan for managing the use of Ada exceptions at the application level.

Rules
EXU01, EXU02, EXU03, EXU04

Exceptions in modern languages present the software architect with a dilemma. On one hand, exceptions can increase integrity by allowing components to signal specific errors in a manner that cannot be ignored, and, in general, allow residual errors to be caught. (Although there should be no unexpected errors in high integrity code, there may be some such errors due, for example, to unforeseeable events such as radiation-induced single-event upsets.) On the other hand, unmanaged use of exceptions increases verification expense and difficulty, especially flow analysis, perhaps to an untenable degree. In that case overall integrity is reduced or unwarranted.

In addition, programming languages may define some system-level errors in terms of language-defined exceptions. Such exceptions may be unavoidable, at least at the system level. For example, in Ada, stack overflow is signalled with the language-defined `Storage_Error` exception. Other system events, such as bus error, may also be mapped to language-defined or vendor-defined exceptions.

Complicating the issue further is the fact that, if exceptions are completely disallowed, there will be no exception handling code in the underlying run-time library. The effects are unpredictable if any exception actually does occur.

Therefore, for the application software the system software architect must decide whether to allow exceptions at all, and if they are to be used, decide the degree and manner of their usage. At the system level, the architect must identify the exceptions that are possible and how they will be addressed.

98.1 Do Not Raise Language-Defined Exceptions (EXU01)

Remediation → Low

Verification Method → GNATcheck rule: `Raising_Predefined_Exceptions` (builtin rule)

98.1.1 Reference

[SEI-Java] ERR07-J

98.1.2 Description

In no case should the application explicitly raise a language-defined exception.

The Ada language-defined exceptions are raised implicitly in specific circumstances defined by the language standard. Explicitly raising these exceptions would be confusing to application developers. The potential for confusion increases as the exception is propagated up the dynamic call chain, away from the point of the `raise` statement, because this increases the number of paths and thus corresponding language-defined checks that could have been the cause.

Verification Method → GNATcheck rule: `Unhandled_Exceptions` (supplied with document)

98.2.1 Reference

N/A

98.2.2 Description

All application-defined exceptions must have at least one corresponding handler that is applicable. Otherwise, if an exception is raised, undesirable behavior is possible. The term *applicable* means that there is no dynamic call chain that can reach the active exception which does not also include a handler that will be invoked for that exception, somewhere in that chain.

When an unhandled exception occurs in the sequence of statements of an application task and propagates to task's body, the task terminates abnormally. No *notification* of some sort is required or defined by the language, although some vendors' implementations may print out a log message or provide some other non-standard response. (Note that such a notification implies an external persistent environment, such as an operating system, that may not be present in all platforms.) The task failure does not affect any other tasks unless those other tasks attempt to communicate with it. In short, failure is silent.

Although the language-defined package `Ada.Task_Termination` can be used to provide a response using standard facilities, not all run-time libraries provide that package. For example, under the Ravenscar profile, application tasks are not intended to terminate, neither normally nor abnormally, and the language does not define what happens if they do. A run-time library for a memory-constrained target, especially a bare-metal target without an operating system, might not include any support for task termination when the tasking model is Ravenscar. The effects of task termination in that case are not defined by the language.

When an unhandled exception occurrence reaches the main subprogram and is not handled there, the exception occurrence is propagated to the environment task, which then completes abnormally. Even if the main subprogram does handle the exception, the environment task still completes (normally in that case).

When the environment task completes (normally or abnormally) it waits for the completion of dependent application tasks, if any. Those dependent tasks continue executing normally, i.e., they do not complete as a result of the environment task completion. Alternatively, however, instead of waiting for them, the implementation has permission to abort the dependent application tasks, per Ada Reference Manual: 10.2 (30) Program Execution[529] The resulting application-specific effect is undefined.

Finally, whether the environment task waited for the dependent tasks or aborted them, the semantics of further execution beyond that point are undefined. There is no concept of a calling environment beyond the environment task (Ada Reference Manual: 10.2 (30) Program Execution[530]). In some systems there is no calling environment, such as bare-metal platforms with only an Ada run-time library and no operating system.

Verification Method → Compiler restrictions

98.4.1 Reference

MISRA C Rule 1.3: "There shall be no occurrence of undefined or critical unspecified behaviour."

98.4.2 Description

In many high-integrity systems the possible responses to an exception are limited or nonexistent. In these cases the only approach is to prove exceptions cannot occur in the first place. Additionally, the cost of proving exceptions cannot happen may be less than the cost of analyzing code in which they are allowed to be raised.

The restriction `No_Exceptions` can be used with **`pragma`** *`Restrictions`* to enforce this approach. Specifically, the restriction ensures that **`raise`** statements and exception handlers

do not appear in the source code and that language-defined checks are not emitted by the compiler. However, a run-time check performed automatically by the hardware is permitted because it typically cannot be prevented. An example of such a check would be traps on invalid addresses. If a hardware check fails, or if an omitted language-defined check would have failed, execution is unpredictable. As a result, enforcement with the restriction is not ideal. However, proof of the absence of run-time errors is possible using the SPARK subset of Ada.

98.4.3 Applicable Vulnerability within ISO TR 24772-2

N/A

98.4.4 Applicable Common Weakness Enumeration

- **CWE-248 - Uncaught Exception**[533]

98.4.5 Noncompliant Code Example

N/A

98.4.6 Compliant Code Example

N/A

98.4.7 Notes

This restriction is detected by SPARK, in which any statements explicitly raising an exception must be proven unreachable (or proof fails and the failure is indicated), and any possibility of run-time exception should be proved not to happen.

OBJECT-ORIENTED PROGRAMMING (OOP)

Goal

Maintainability
✓

Reliability
✓

Portability
Performance
Security
✓

Description
Have a plan for selecting the OOP facilities of the language to use.

Rules
OOP01, OOP02, OOP03, OOP04, OOP05, OOP06, OOP07

There are many issues to consider when planning the use of Object Oriented features in a high-integrity application. Choices should be made based on the desired expressive power of the OO features and the required level of certification or safety case.

For example, the use of inheritance can provide abstraction and separation of concerns. However, the extensive use of inheritance, particularly in deep hierarchies, can lead to fragile code bases.

Similarly, when new types of entities are added, dynamic dispatching provides separation of the code that must change from the code that manipulates those types and need not be changed to handle new types. However, analysis of dynamic dispatching must consider every candidate object type and analyze the associated subprogram for appropriate behavior.

Therefore, the system architect has available a range of possibilities for the use of OOP constructs, with tool enforcement available for the selections. Note that full use of OOP, including dynamic dispatching, may not be unreasonable.

The following rules assume use of tagged types, a requirement for full OOP in Ada.

N/A

99.1.2 Description

In this approach, tagged types are allowed and type extension (inheritance) is allowed, but there are no class-wide constructs.

This restriction ensures there are no class-wide objects or formal parameters, nor access types designating class-wide types.

In this approach there are no possible dynamic dispatching calls because such calls can only occur when a class-wide value is passed as the parameter to a primitive operation of a tagged type.

99.2.2 Description

In this approach, class-wide constructs are allowed, as well as tagged types and type extension (inheritance), but dynamic dispatching remains disallowed (i.e., as in OOP01).

This rule ensures there are no class-wide values passed as the parameter to a primitive operation of a tagged type, hence there are no dynamically dispatched calls.

Note that this rule should not be applied without due consideration.

Verification Method → GNATcheck rule: `Deep_Inheritance_Hierarchies:2` (builtin rule)

99.3.1 Reference

[AdaOOP2016] section 5.1

99.3.2 Description

A class inheritance hierarchy consists of a set of types related by inheritance. Each class, other than the root class, is a subclass of other classes, and each, except for "leaf" nodes, is a base class for those that are derived from it.

Improperly designed inheritance hierarchies complicate system maintenance and increase the effort in safety certification, in any programming language.

A common characteristic of problematic hierarchies is "excessive" depth, in which a given class is a subclass of many other classes. Depth can be a problem because a change to a class likely requires inspection, modification, recompilation, and retesting/reverification of all classes below it in the hierarchy. The extent of that effect increases as we approach the root class. This rippling effect is known as the *fragile base class* problem. Clearly, the greater the depth the more subclasses there are to be potentially affected. In addition, note that a change to one class may cause a cascade of other secondary changes to subclasses, so the effect is often not limited to a single change made to all the subclasses in question.

Deep inheritance hierarchies also contribute to complexity, rather than lessening it, by requiring the reader to understand multiple superclasses in order to understand the behavior of a given subclass.

99.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.41 Inheritance [RIP]

99.3.4 Applicable Common Weakness Enumeration

- **CWE-1074 - Class with Excessively Deep Inheritance**[534]
- **CWE-1086 - Class with Excessive Number of Child Classes**[535]

99.3.5 Noncompliant Code Example

The threshold for "too deep" is inexact, but beyond around 4 or 5 levels the complexity accelerates rapidly.

```
type Shape_T is tagged private;
procedure Set_Name (Shape : Shape_T; Name  : String);
function Get_Name (Shape : Shape_T) return String;

type Quadrilateral_T is new Shape_T with private;
type Trapezoid_T is new Quadrilateral_T with private;
type Parallelogram_T is new Trapezoid_T with private;
type Rectangle_T is new Parallelogram_T with private;
type Square_T is new Rectangle_T with private;
```

99.3.6 Compliant Code Example

```
type Shape_T is tagged private;
procedure Set_Name (Shape : Shape_T; Name  : String);
function Get_Name (Shape : Shape_T) return String;

type Quadrilateral_T is new Shape_T with private;
type Rectangle_T is new Quadrilateral_T with private;
type Square_T is new Rectangle_T with private;
```

Remediation → Medium (easy fix, but a difficult to detect bug)

Verification Method → GNATcheck rule: `Direct_Calls_To_Primitives` (builtin rule)

99.4.1 Reference

N/A

99.4.2 Description

This rule applies only to tagged types, when visibly tagged at the point of a call from one primitive to another of that same type.

By default, subprogram calls are statically dispatched. Dynamic dispatching only occurs when a class-wide value is passed to a primitive operation of a specific type. Forcing an otherwise optional dynamic dispatching call in this case is known as *redispatching.*

When one primitive operation of a given tagged type invokes another distinct primitive operation of that same type, use redispatching so that an overriding version of that other primitive will be invoked if it exists. Otherwise an existing overridden version would not be invoked, which is very likely an error.

This rule does not apply to the common case in which an overriding of a primitive operation calls the "parent" type's version of the overridden operation. Such calls occur in the overridden body when the new version is not replacing, but rather, is augmenting the parent type's version. In this case the new version must do whatever the parent version did, and can then add functionality specific to the new type.

By default, this rule applies to another common case in which static calls from one primitive operation to another make sense. Specifically, *constructors* are often implemented in Ada as functions that create a new value of the tagged type. As constructors, these functions are type-specific. They must call the primitive operations of the type being created, not operations that may be overridden for some type later derived from it. (Note that there is a GNATcheck rule parameter to not flag this case.)

Typically constructor functions only have the tagged type as the result type, not as the type for formal parameters, if any, because actual parameters of the tagged type would themselves likely require construction. This specific usage is the case ignored by the GNATcheck rule parameter.

Note that constructors implemented as procedures also call primitive operations of the specific type, for the same reasons as constructor functions. This usage is allowed by this rule and does not require the GNATcheck parameter. (The difference between function and procedure constructors is that these procedures will have a formal parameter of the tagged type, of mode `out`.)

99.5.1 Reference

[AdaOOP2016] section 4.3

99.5.2 Description

The declaration of a primitive operation that overrides an inherited operation must include an explicit **`overriding`** annotation.

The semantics of inheritance in mainstream object-oriented languages may result in two kinds of programming errors: 1) intending, but failing, to override an inherited subprogram, and 2) intending not to override an inherited subprogram, but doing so anyway. Because an overridden subprogram may perform subclass-specific safety or security checks, the invocation of the parent subprogram on a subclass instance can introduce a vulnerability.

The first issue (intending but failing to override) typically occurs when the subprogram name is misspelled. In this case a new or overloaded subprogram is actually declared.

The second issue (unintended overriding) can arise when a new subprogram is added to a parent type in an existing inheritance hierarchy. The new subprogram happens to cause one or more inherited subprograms below it to override the new superclass version. This mistake typically happens during program maintenance.

In Ada, much like other modern languages, one can annotate a subprogram declaration (and body) with an indication that the subprogram is an overriding of an inherited version. This is done with the **`overriding`** reserved word preceding the subprogram specification.

Similarly, in Ada one can explicitly indicate that a subprogram is not an overriding. To do so, the programmer includes the reserved words **`not overriding`** immediately prior to the subprogram specification.

Of course, incorrect marking errors are flagged by the compiler. If a subprogram is explicitly marked as overriding but is not actually overriding, the compiler will reject the code. Likewise, if a primitive subprogram is explicitly marked as not overriding, but actually is overriding, the compiler will reject the code.

However, most subprograms are not overriding so it would be a heavy burden on the programmer to make them explicitly indicate that fact. That's not to mention the relatively heavy syntax required.

In addition, both annotations are optional for the sake of compatibility with prior versions of the language. Therefore, a subprogram without either annotation might or might not be overriding. A legal program could contain some explicitly annotated subprograms and some that are not annotated at all. But because the compiler will reject explicit annotations that are incorrect, all we require is that one of the two cases be explicitly indicated for all such subprograms. Any unannotated subprograms not flagged as errors are then necessarily not that case, they must be the other one.

Since overriding is less common and involves slightly less syntax to annotate, the guideline requires explicit annotations only for overriding subprograms. It follows that any subprograms not flagged as errors by the compiler are not overriding, so they need not be marked explicitly as such.

This guideline is implemented by compiler switches, or alternatively, by a GNATcheck rule (specified below the table). With this guideline applied and enforced, the two inheritance errors described in the introduction cannot happen.

Note that the compiler switches will also require the explicit overriding indicator when overriding a language-defined operator. The switches also apply to inherited primitive subprograms for non-tagged types.

99.5.3 Applicable Vulnerability within ISO TR 24772-2

- 6.34 Subprogram signature mismatch [OTR]
- 6.41 Inheritance [RIP]

99.5.4 Applicable Common Weakness Enumeration

- **CWE-685 - Function Call With Incorrect Number of Arguments**[536]

99.5.5 Noncompliant Code Example

```
type Root_T is tagged null record;
procedure Primitive (X : in out Root_T) is null;
```

```
type Noncompliant_Child_T is new Root_T with null record;
procedure Primitive (X : in out Noncompliant_Child_T) is null;
```

99.5.6 Compliant Code Example

```
type Compliant_Child_T is new Root_T with null record;
overriding procedure Primitive (X : in out Compliant_Child_T) is null;
```

99.5.7 Notes

This rule requires the GNAT compiler switches `-gnaty0` and `-gnatwe` in order for the compiler to flag missing overriding annotations as errors. The first causes the compiler to generate the warnings, and the second causes those warnings to be treated as errors.

Verification Method → GNATcheck rule: `Specific_Pre_Post` (builtin rule)

99.6.1 Reference

[AdaOOP2016] section 6.1.4

SPARK User's Guide, section 7.5.2[537]

99.6.2 Description

For primitive operations of tagged types, use only class-wide pre/post contracts, if any.

The class-wide form of precondition and postcondition expresses conditions that are intended to apply to any version of the subprogram. Therefore, when a subprogram is derived as part of inheritance, only the class-wide form of those contracts is inherited from the parent subprogram, if any are defined. As a result, it only makes sense to use the class-wide form in this situation.

(The same semantics and recommendation applies to type invariants.)

Note: this approach will be required for OOP07 (Ensure Local Type Consistency).

99.7.1 Reference

[AdaOOP2016] See section 4.2.

GNAT User's Guide, section 5.10.11[538]

99.7.2 Description

Either:

- Formally verify local type consistency, or
- Ensure that each tagged type passes all the tests of all the parent types which it can replace.

Rationale:

One of the fundamental benefits of OOP is the ability to manipulate objects in a class inheritance hierarchy without "knowing" at compile-time the specific classes of the objects being manipulated. By *manipulate* we mean invoking the primitive operations, the *methods* defined by the classes.

[538] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/gnat_utility_programs.html

We will use the words *class* and *type* interchangeably, because classes are composed in Ada and SPARK using a combination of building blocks, especially type declarations. However, we will use the term *subclass* rather than *subtype* because the latter has a specific meaning in Ada and SPARK that is unrelated to OOP.

The objects whose operations are being invoked can be of types anywhere in the inheritance tree, from the root down to the bottom. The location, i.e., the specific type, is transparent to the manipulating code. This type transparency is possible because the invoked operations are dynamically dispatched at run-time, rather than statically dispatched at compile-time.

Typically, the code manipulating the objects does so in terms of superclasses closer to the root of the inheritance tree. Doing so increases generality because it increases the number of potential subclasses that can be manipulated. The actual superclass chosen will depend on the operations required by the manipulation. In Ada and SPARK, subclasses can add operations but can never remove them, so more operations are found as we move down from the root. That is the nature of specialization. Note that the guarantee of an invoked operations' existence is essential for languages used in this domain.

However, for this transparent manipulation to be functionally correct — to accomplish what the caller intends — the primitive operations of subclasses must be functionally indistinguishable from those of the superclasses. That doesn't mean the subclasses cannot make changes. Indeed, the entire point of subclasses is to make changes. In particular, functional changes can be either introduction of new operations, or overridings of inherited operations. It is these overridings that must be functionally transparent to the manipulating code. (Of course, for an inherited operation that is not overridden, the functionality is inherited as-is, and is thus transparent trivially.)

The concept of functional transparency was introduced, albeit with different terminology, by Liskov and Wing in 1994 [LiskovWing1994] and is, therefore, known as the Liskov Substitution Principle, or LSP. The *substitution* in LSP means that a subclass must be substitutable for its superclass, i.e., a subclass instance should be usable whenever a superclass instance is required.

Unfortunately, requirements-based testing will not detect violations of LSP because unit-level requirements do not concern themselves with superclass substitutability.

However, the OO supplement of DO-178C [DO178C] offers solutions, two of which are in fact the options recommended by this guideline.

Specifically, the supplement suggests adding a specific verification activity it defines as Local Type Consistency Verification. This activity ensures LSP is respected and, in so doing, addresses the vulnerability.

Verification can be accomplished statically with formal methods in SPARK, or dynamically via a modified form of testing.

For the static approach, type consistency is verified by examining the properties of the overriding operation's preconditions and postconditions. These are the properties required by Design by Contract, as codified by Bertrand Meyer [Meyer1997]. Specifically, an overridden primitive may only replace the precondition with one weaker than that of the parent version, and may only replace the postcondition with one stronger. In essence, relative to the parent version, an overridden operation can only require the same or less, and provide the same or more. Satisfying that requirement is sufficient to ensure functional transparency because the manipulating code only "knows" the contracts of the class it manipulates, i.e., the view presented by the type, which may very well be a superclass of the one actually invoked.

In Ada and SPARK, the class-wide form of preconditions and postconditions are inherited by overridden primitive operations of tagged types. The inherited precondition and that of the overriding (if any) are combined into a conjunction. All must hold, otherwise the precondition fails. Likewise, the inherited postcondition is combined with the overriding postcondition into a disjunction. At least one of them must hold. In Ada these are tested

at run-time. In SPARK, they are verified statically (or not, in which case proof fails and an error is indicated).

To verify substitutability via testing, all the tests for all superclass types are applied to objects of the given subclass type. If all the parent tests pass, this provides a high degree of confidence that objects of the new tagged type can properly substitute for parent type objects. Note that static proof of consistency provides an even higher degree of confidence.

99.7.3 Applicable Vulnerability within ISO TR 24772-2

- 6.42 Violations of the Liskov substitution principle of the contract model [BLP]
- 6.43 Redispatching [PPH]
- 6.44 Polymorphic variables [BKK]

99.7.4 Applicable Common Weakness Enumeration

N/A

99.7.5 Noncompliant Code Example

```
package P is
   pragma Elaborate_Body;
   type Rectangle is tagged private;
   procedure Set_Width (This  : in out Rectangle;
                        Value : Positive)
   with
      Post => Width (This) = Value and
              Height (This) = Height (This'Old);

   function Width (This : Rectangle) return Positive;

   procedure Set_Height (This  : in out Rectangle;
                         Value : Positive)
   with
      Post => Height (This) = Value and
              Width (This) = Width (This'Old);

   function Height (This : Rectangle) return Positive;

private
   ...
end P;
```

The postcondition for `Set_Width` states that the `Height` is not changed. Likewise, for `Set_Height`, the postcondition asserts that the `Width` is not changed. However, these postconditions are not class-wide so they are not inherited by subclasses.

Now, in a subclass `Square`, the operations are overridden so that setting the width also sets the height to the same value, and vice versa. Thus the overridden operations do not maintain type consistency, but this fact is neither detected at run-time, nor could SPARK verify it statically (and SPARK is not used at all in these versions of the packages).

```
with P; use P;
package Q is
   pragma Elaborate_Body;
   type Square is new Rectangle with private;

   overriding
   procedure Set_Width (This  : in out Square;
```

(continues on next page)

(continued from previous page)

```
                      Value : Positive)
   with
  Post => Width (This) = Height (This);

   overriding
   procedure Set_Height (This  : in out Square;
                         Value : Positive)
   with
  Post  => Width (This) = Height (This);

private
   ...
end Q;
```

99.7.6 Compliant Code Example

```
package P with SPARK_Mode is
   pragma Elaborate_Body;
   type Rectangle is tagged private;

   procedure Set_Width (This  : in out Rectangle;
                        Value : Positive)
   with
      Post'Class => Width (This) = Value and
                    Height (This) = Height (This'Old);

   function Width (This : Rectangle) return Positive;

   procedure Set_Height (This  : in out Rectangle;
                         Value : Positive)
   with
      Post'Class => Height (This) = Value and
                    Width (This) = Width (This'Old);

   function Height (This : Rectangle) return Positive;

private
   ...
end P;
```

Now the postconditions are class-wide so they are inherited by subclasses. In the subclass Square, the postconditions will not hold at run-time. Likewise, SPARK can now prove that type consistency is not verified because the postconditions are weaker than those inherited:

```
with P; use P;
package Q with SPARK_Mode is
   pragma Elaborate_Body;
   type Square is new Rectangle with private;

   overriding
   procedure Set_Width (This  : in out Square;
                        Value : Positive)
   with
  Post'Class => Width (This) = Height (This);

   overriding
   procedure Set_Height (This  : in out Square;
                         Value : Positive)
   with
  Post'Class => Width (This) = Height (This);
```

(continues on next page)

(continued from previous page)

```
private
   type Square is new Rectangle with null record;
end Q;
```

99.7.7 Notes

Verification can be achieved dynamically with the GNATtest tool, using the `--validate-type-extensions` switch. SPARK enforces this rule.

Verification Method → Compiler restrictions

100.2.1 Reference

Power of 10 rule #10: "All code must be compiled, from the first day of development, with all compiler warnings enabled at the most pedantic setting available. All code must compile without warnings."

100.2.2 Description

The Ada compiler does a degree of static analysis itself, and generates many warnings when they are enabled. These warnings likely indicate very real problems so they should be examined and addressed, either by changing the code or disabling the warning for the specific occurrence flagged in the source code.

To ensure that warnings are examined and addressed one way or the other, the compiler must be configured to treat warnings as errors, i.e., preventing object code generation.

Note that warnings will occasionally be given for code usage that is intentional. In those cases the warnings should be disabled by using `pragma Warnings` with the parameter `Off`, and a string indicating the error message to be disabled. In other cases, a different mechanism might be appropriate, such as aspect (or pragma) `Unreferenced`.

100.2.3 Applicable Vulnerability within ISO TR 24772-2

- 6.18 Dead Store [WXQ]
- 6.19 Unused variable [YZS]
- 6.20 Identifier name reuse [YOW]
- 6.22 Initialization of variables [LAV]

100.2.4 Applicable Common Weakness Enumeration

- **CWE-1127 - Compilation with Insufficient Warnings or Errors**[542]

100.2.5 Noncompliant Code Example

```
procedure P (This : Obj) is
begin
   ... code not referencing This
end P;
```

The formal parameter controls dispatching for the sake of selecting the subprogram to be called but does not participate in the implementation of the body.

[542] https://cwe.mitre.org/data/definitions/1127.html

100.2.6 Compliant Code Example

```
procedure P (This : Obj) is
   pragma Unreferenced (This);
begin
   ... code not referencing This
end P;
```

The compiler will no longer issue a warning that the formal parameter `This` is not referenced. Of course, if that changes and `This` becomes referenced, the compiler will flag the `pragma`.

100.2.7 Notes

This rule can be applied via the GNAT `-gnatwae` compiler switch, which both enables warnings and treats them as errors. Note that the switch enables almost all optional warnings, but not all. Some optional warnings correspond to very specific circumstances, and would otherwise generate too much noise for their value.

100.3 Use a Static Analysis Tool Extensively (SWE03)

Remediation → High

Verification Method → Static analysis tools

100.3.1 Reference

Power of 10 rule #10: "All code must also be checked daily with at least one, but preferably more than one, strong static source code analyzer and should pass all analyses with zero warnings."

100.3.2 Description

If not using SPARK for regular development, use a static analyzer, such as CodePeer, extensively. No warnings or errors should remain unresolved at the given level adopted for analysis (which can be selected to adjust the false positive ratio).

Specifically, any code checked into the configuration management system must be checked by the analyzer and be error-free prior to check-in. Similarly, each nightly build should produce a CodePeer baseline for the project.

100.3.3 Applicable Vulnerability within ISO TR 24772-2

- 6.6 Conversion errors [FLC]
- 6.18 Dead store [WXQ]
- 6.19 Unused variable [YZS]
- 6.20 Identifier name reuse [YOW]
- 6.24 Side-effects and order of evaluation [SAM]
- 6.25 Likely incorrect expression [KOA]

100.3.4 Applicable Common Weakness Enumeration

N/A

100.3.5 Noncompliant Code Example

N/A

100.3.6 Compliant Code Example

N/A

100.3.7 Notes

CodePeer is the recommended static analyzer. Note that CodePeer can detect GNATcheck rule violations (via the `--gnatcheck` CodePeer switch and a rules file).

100.4 Hide Implementation Artifacts (SWE04)

Remediation → High, as retrofit can be extensive

Verification Method → GNATcheck rule: `Visible_Components` (builtin rule)

100.4.1 Reference

MISRA C Rule 8.7: "Functions and objects should not be defined with external linkage if they are referenced in only one translation unit."

100.4.2 Description

Do not make implementation artifacts compile-time visible to clients. Only make available those declarations that define the abstraction presented to clients by the component. In other words, define Abstract Data Types and use the language to enforce the abstraction. This is a fundamental Object-Oriented Design principle.

This guideline minimizes client dependencies and thus allows the maximum flexibility for changes in the underlying implementation. It minimizes the editing changes required for client code when implementation changes are made.

This guideline also limits the region of code required to find any bugs to the package and child packages, if any, defining the abstraction.

This guideline is to be followed extensively as the design default for components. Once the application code size becomes non-trivial, the cost of retrofit is extremely high.

100.4.3 Applicable Vulnerability within ISO TR 24772-2

N/A

100.4.4 Applicable Common Weakness Enumeration

- **CWE-496 - Public Data Assigned to Private Array-Typed Field**[543]
- **CWE-1061 - Insufficient Encapsulation**[544]

100.4.5 Noncompliant Code Example

```
package Noncompliant is
   type Content_T is array (Capacity_T range <>) of Integer;
   type Stack_T (Capacity : Capacity_T) is tagged record
      Content : Content_T (1 .. Capacity);
      Top     : Capacity_T := 0;
   end record;
   procedure Push
     (Stack : in out Stack_T;
      Item  :        Integer);
   procedure Pop
     (Stack : in out Stack_T;
      Item  :    out Integer);
end Noncompliant;
```

[543] https://cwe.mitre.org/data/definitions/496.html
[544] https://cwe.mitre.org/data/definitions/1061.html

Note that both type Content_T, as well as the record type components of type Stack_T, are visible to clients. Client code may declare variables of type Content_T and may directly access and modify the record components. Bugs introduced via this access could be anywhere in the entire client codebase.

100.4.6 Compliant Code Example

```
package Compliant is
   type Stack_T (Capacity : Capacity_T) is tagged private;
   procedure Push
     (Stack : in out Stack_T;
      Item  :        Integer);
   procedure Pop
     (Stack : in out Stack_T;
      Item  :    out Integer);
private
   type Content_T is array (Capacity_T range <>) of Integer;
   type Stack_T (Capacity : Capacity_T) is tagged record
      Content : Content_T (1 .. Capacity);
      Top     : Capacity_T := 0;
   end record;
end Compliant;
```

Type Content_T, as well as the record type components of type Stack_T, are no longer visible to clients. Any bugs in the stack processing code must be in this package, or its child packages, if any.

100.4.7 Notes

The GNATcheck rule specified above is not exhaustive.

What's New in Ada 2022

Copyright © 2022 – 2023, AdaCore

This book is published under a CC BY-SA license, which means that you can copy, redistribute, remix, transform, and build upon the content for any purpose, even commercially, as long as you give appropriate credit, provide a link to the license, and indicate if changes were made. If you remix, transform, or build upon the material, you must distribute your contributions under the same license as the original. You can find license details on this page[550]

This course presents an overview of the new features of the latest Ada 2022 standard.

This document was written by Maxim Reznik and reviewed by Richard Kenner.

Note

The code examples in this course use an 80-column limit, which is a typical limit for Ada code. Note that, on devices with a small screen size, some code examples might be difficult to read.

Note

Each code example from this book has an associated "code block metadata", which contains the name of the "project" and an MD5 hash value. This information is used to identify a single code example.

You can find all code examples in a zip file, which you can download from the learn website[551]. The directory structure in the zip file is based on the code block metadata. For example, if you're searching for a code example with this metadata:

- Project: Courses.Intro_To_Ada.Imperative_Language.Greet
- MD5: cba89a34b87c9dfa71533d982d05e6ab

you will find it in this directory:

```
projects/Courses/Intro_To_Ada/Imperative_Language/Greet/
cba89a34b87c9dfa71533d982d05e6ab/
```

In order to use this code example, just follow these steps:

1. Unpack the zip file;
2. Go to target directory;
3. Start GNAT Studio on this directory;
4. Build (or compile) the project;
5. Run the application (if a main procedure is available in the project).

CHAPTER

TWO

INTRODUCTION

This is a collection of short code examples demonstrating new features of the Ada 2022 Standard[552] as they are implemented in GNAT Ada compiler.

To use some of these features, you may need to use a compiler command line switch or pragma. Compilers starting with GNAT Community Edition 2021[553] or GCC 11[554] use `pragma Ada_2022;` or the `-gnat2022` switch.

CHAPTER

THREE

'IMAGE ATTRIBUTE FOR ANY TYPE

Note

Attribute 'Image for any type is supported by

- GNAT Community Edition 2020 and later
- GCC 11

103.1 'Image attribute for a value

Since the publication of the Technical Corrigendum 1[556] in February 2016, the 'Image attribute can now be applied to a value. So instead of My_Type'Image (Value), you can just write Value'Image, as long as the Value is a name[557]. These two statements are equivalent:

```
Ada.Text_IO.Put_Line (Ada.Text_IO.Page_Length'Image);

Ada.Text_IO.Put_Line
  (Ada.Text_IO.Count'Image (Ada.Text_IO.Page_Length));
```

103.2 'Image attribute for any type

In Ada 2022, you can apply the 'Image attribute to any type, including records, arrays, access types, and private types. Let's see how this works. We'll define array, record, and access types and corresponding objects and then convert these objects to strings and print them:

Listing 2624: main.adb

```
1  with Ada.Text_IO;
2
3  procedure Main is
4     type Vector is array (Positive range <>) of Integer;
5
6     V1 : aliased Vector := [1, 2, 3];
7
8     type Text_Position is record
9        Line, Column : Positive;
10    end record;
11
```

(continues on next page)

[556] https://reznikmm.github.io/ada-auth/rm-4-NC/RM-0-1.html
[557] https://reznikmm.github.io/ada-auth/rm-4-NC/RM-4-1.html#S0091

(continued from previous page)

```
12    Pos : constant Text_Position := (Line => 10, Column => 3);
13
14    type Vector_Access is access all Vector;
15
16    V1_Ptr : constant Vector_Access := V1'Access;
17
18 begin
19    Ada.Text_IO.Put_Line (V1'Image);
20    Ada.Text_IO.Put_Line (Pos'Image);
21    Ada.Text_IO.New_Line;
22    Ada.Text_IO.Put_Line (V1_Ptr'Image);
23 end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Image_Attribute
MD5: c58d3133c45d780305a2b5c88d159764
```

Runtime output

```
[ 1,  2,  3]

(LINE =>  10,
 COLUMN =>  3)

(access 7ffe67a30fa8)
```

```
$ gprbuild -q -P main.gpr
  Build completed successfully.
$ ./main
  [ 1,  2,  3]
  (LINE =>  10,
   COLUMN =>  3)
  (access 7fff64b23988)
```

Note the square brackets in the array image output. In Ada 2022, array aggregates could be written *this way* (page 2253)!

CHAPTER

FOUR

REDEFINING THE 'IMAGE ATTRIBUTE

In Ada 2022, you can redefine 'Image attribute for your type, though the syntax to do this has been changed several times. Let's see how it works in GNAT Community 2021.

Note

Redefining attribute 'Image is supported by

- GNAT Community Edition 2021 (using Text_Buffers)
- GNAT Community Edition 2020 (using Text_Output.Utils)
- GCC 11 (using Text_Output.Utils)

In our example, let's redefine the 'Image attribute for a location in source code. To do this, we provide a new Put_Image aspect for the type:

Listing 2625: main.adb

```
with Ada.Text_IO;
with Ada.Strings.Text_Buffers;

procedure Main is

   type Source_Location is record
      Line   : Positive;
      Column : Positive;
   end record
     with Put_Image => My_Put_Image;

   procedure My_Put_Image
     (Output : in out Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
      Value  : Source_Location);

   procedure My_Put_Image
     (Output : in out Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
      Value  : Source_Location)
   is
      Line   : constant String := Value.Line'Image;
      Column : constant String := Value.Column'Image;
      Result : constant String :=
        Line (2 .. Line'Last) & ':' & Column (2 .. Column'Last);
   begin
       Output.Put (Result);
   end My_Put_Image;

   Line_10 : constant Source_Location := (Line => 10, Column => 1);

begin
```

(continues on next page)

(continued from previous page)

```
31    Ada.Text_IO.Put_Line (Line_10'Image);
32 end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Image_Redefine
MD5: 4c77a3589eaba3a4c1b70200913ad6b8
```

Runtime output

```
10:1
```

104.1 What's the Root_Buffer_Type?

Let's see how it's defined in the `Ada.Strings.Text_Buffers` package.

```
type Root_Buffer_Type is abstract tagged limited private;

procedure Put
  (Buffer : in out Root_Buffer_Type;
   Item   : in     String) is abstract;
```

In addition to `Put`, there are also `Wide_Put`, `Wide_Wide_Put`, `Put_UTF_8`, `Wide_Put_UTF_16`. And also `New_Line`, `Increase_Indent`, `Decrease_Indent`.

104.2 Outdated draft implementation

GNAT Community Edition 2020 and GCC 11 both provide a draft implementation that's incompatible with the Ada 2022 specification. For those versions, `My_Put_Image` looks like:

```
procedure My_Put_Image
  (Sink  : in out Ada.Strings.Text_Output.Sink'Class;
   Value : Source_Location)
is
   Line   : constant String := Value.Line'Image;
   Column : constant String := Value.Column'Image;
   Result : constant String :=
     Line (2 .. Line'Last) & ':' & Column (2 .. Column'Last);
begin
    Ada.Strings.Text_Output.Utils.Put_UTF_8 (Sink, Result);
end My_Put_Image;
```

CHAPTER

FIVE

USER-DEFINED LITERALS

Note

User-defined literals are supported by

- GNAT Community Edition 2020
- GCC 11

In Ada 2022, you can define string, integer, or real literals for your types. The compiler will convert such literals to your type at run time using a function you provide. To do so, specify one or more new aspects:

- `Integer_Literal`
- `Real_Literal`
- `String_Literal`

For our example, let's define all three for a simple type and see how they work. For simplicity, we use a `Wide_Wide_String` component for the internal representation:

Listing 2626: my_types.ads

```
with Ada.Characters.Conversions;

package My_Types is

   type My_Type (Length : Natural) is record
      Value : Wide_Wide_String (1 .. Length);
   end record
     with String_Literal => From_String,
       Real_Literal      => From_Real,
       Integer_Literal   => From_Integer;

   function From_String (Value : Wide_Wide_String) return My_Type is
      ((Length => Value'Length, Value => Value));

   function From_Real (Value : String) return My_Type is
      ((Length => Value'Length,
        Value  => Ada.Characters.Conversions.To_Wide_Wide_String (Value)));

   function From_Integer (Value : String) return My_Type renames From_Real;

end My_Types;
```

Listing 2627: main.adb

```
with Ada.Wide_Wide_Text_IO;
with My_Types; use My_Types;

procedure Main is

   procedure Print (Self : My_Type) is
   begin
      Ada.Wide_Wide_Text_IO.Put_Line (Self.Value);
   end Print;

begin
   Print ("Test ""string""");
   Print (123);
   Print (16#DEAD_BEEF#);
   Print (2.99_792_458e+8);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.User_Defined_Literals
MD5: d63d84934cc3ab35861a07384d1d7535
```

Runtime output

```
Test "string"
123
16#DEAD_BEEF#
2.99_792_458e+8
```

As you see, real and integer literals are converted to strings while preserving the formatting in the source code, while string literals are decoded: `From_String` is passed the specified string value. In all cases, the compiler translates these literals into function calls.

105.1 Turn Ada into JavaScript

Do you know that *'5'+3* in JavaScript is *53*?

```
> '5'+3
'53'
```

Now we can get the same result in Ada! But before we do, we need to define a custom `+` operator:

Listing 2628: my_types.ads

```
with Ada.Characters.Conversions;

package My_Types is

   type My_Type (Length : Natural) is record
      Value : Wide_Wide_String (1 .. Length);
   end record
     with String_Literal => From_String,
       Real_Literal      => From_Real,
       Integer_Literal   => From_Integer;

   function "+" (Left, Right : My_Type) return My_Type is
```

(continues on next page)

(continued from previous page)

```
      (Left.Length + Right.Length, Left.Value & Right.Value);

   function From_String (Value : Wide_Wide_String) return My_Type is
      ((Length => Value'Length, Value => Value));

   function From_Real (Value : String) return My_Type is
      ((Length => Value'Length,
        Value  => Ada.Characters.Conversions.To_Wide_Wide_String (Value)));

   function From_Integer (Value : String) return My_Type renames From_Real;

end My_Types;
```

Listing 2629: main.adb

```
with Ada.Wide_Wide_Text_IO;
with My_Types; use My_Types;

procedure Main is

   procedure Print (Self : My_Type) is
   begin
      Ada.Wide_Wide_Text_IO.Put_Line (Self.Value);
   end Print;

begin
   Print ("5" + 3);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.User_Defined_Literals_JS
MD5: f50de03fb3a02404fe536dc5e626d2b3
```

Runtime output

```
53
```

Jokes aside, this feature is very useful. For example it allows a "native-looking API" for *big integers* (page 2273).

CHAPTER

SIX

ADVANCED ARRAY AGGREGATES

Note

These array aggregates are supported by

- GNAT Community Edition 2020
- GCC 11

106.1 Square brackets

In Ada 2022, you can use square brackets in array aggregates. Using square brackets simplifies writing both empty aggregates and single-element aggregates. Consider this:

Listing 2630: show_square_brackets.ads

```
1  package Show_Square_Brackets is
2
3     type Integer_Array is array (Positive range <>) of Integer;
4
5     Old_Style_Empty : Integer_Array := (1 .. 0 => <>);
6     New_Style_Empty : Integer_Array := [];
7
8     Old_Style_One_Item : Integer_Array := (1 => 5);
9     New_Style_One_Item : Integer_Array := [5];
10
11 end Show_Square_Brackets;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Square_Brackets
MD5: 2914b9435684a1eecd2567548969a3ed
```

Short summary for parentheses and brackets

- Record aggregates use parentheses
- *Container aggregates* (page 2257) use square brackets
- Array aggregates can use both square brackets and parentheses, but parentheses usage is obsolescent

106.2 Iterated Component Association

There is a new kind of component association:

```
Vector : Integer_Array := [for J in 1 .. 5 => J * 2];
```

This association starts with **for** keyword, just like a quantified expression. It declares an index parameter that you can use in the computation of a component.

Iterated component associations can nest and can be nested in another association (iterated or not). Here we use this to define a square matrix:

```
Matrix : array (1 .. 3, 1 .. 3) of Positive :=
 [for J in 1 .. 3 =>
   [for K in 1 .. 3 => J * 10 + K]];
```

Iterated component associations in this form provide both element indices and values, just like named component associations:

```
Data : Integer_Array (1 .. 5) :=
  [for J in 2 .. 3 => J, 5 => 5, others => 0];
```

Here `Data` contains `(0, 2, 3, 0, 5)`, not `(2, 3, 5, 0, 0)`.

Another form of iterated component association corresponds to a positional component association and provides just values, but no element indices:

```
Vector_2 : Integer_Array := [for X of Vector => X / 2];
```

You cannot mix these forms in a single aggregate.

It's interesting that such aggregates were originally proposed more than 25 years ago!

Complete code snippet:

Listing 2631: show_iterated_component_association.adb

```
with Ada.Text_IO;

procedure Show_Iterated_Component_Association is

   type Integer_Array is array (Positive range <>) of Integer;

   Old_Style_Empty : Integer_Array := (1 .. 0 => <>);
   New_Style_Empty : Integer_Array := [];

   Old_Style_One_Item : Integer_Array := (1 => 5);
   New_Style_One_Item : Integer_Array := [5];

   Vector : constant Integer_Array := [for J in 1 .. 5 => J * 2];

   Matrix : constant array (1 .. 3, 1 .. 3) of Positive :=
```

(continues on next page)

(continued from previous page)

```
     [for J in 1 .. 3 =>
       [for K in 1 .. 3 => J * 10 + K]];

   Data : constant Integer_Array (1 .. 5) :=
     [for J in 2 .. 3 => J, 5 => 5, others => 0];

   Vector_2 : constant Integer_Array := [for X of Vector => X / 2];
begin
   Ada.Text_IO.Put_Line (Vector'Image);
   Ada.Text_IO.Put_Line (Matrix'Image);
   Ada.Text_IO.Put_Line (Data'Image);
   Ada.Text_IO.Put_Line (Vector_2'Image);
end Show_Iterated_Component_Association;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Iterated_Component_Association
MD5: 9bc822b59c2c423019917728aab75c69
```

Runtime output

```
[ 2,  4,  6,  8,  10]

[
 [ 11,  12,  13],

 [ 21,  22,  23],

 [ 31,  32,  33]]

[ 0,  2,  3,  0,  5]

[ 1,  2,  3,  4,  5]
```

CHAPTER

SEVEN

CONTAINER AGGREGATES

Note

Container aggregates are supported by

- GNAT Community Edition 2021
- GCC 11

Ada 2022 introduces container aggregates, which can be used to easily create values for vectors, lists, maps, and other aggregates. For containers such as maps, the aggregate must use named associations to provide keys and values. For other containers it uses positional associations. Only square brackets are allowed. Here's an example:

Listing 2632: main.adb

```
with Ada.Text_IO;
with Ada.Containers.Vectors;
with Ada.Containers.Ordered_Maps;

procedure Main is

   package Int_Vectors is new Ada.Containers.Vectors
     (Positive, Integer);

   X : constant Int_Vectors.Vector := [1, 2, 3];

   package Float_Maps is new Ada.Containers.Ordered_Maps
     (Integer, Float);

   Y : constant Float_Maps.Map := [-10 => 1.0, 0 => 2.5, 10 => 5.51];
begin
   Ada.Text_IO.Put_Line (X'Image);
   Ada.Text_IO.Put_Line (Y'Image);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Container_Aggregates_1
MD5: 317c252582f75f248a154bd843388aaa
```

Runtime output

```
 [ 1,  2,  3]

 [-10 =>  1.00000E+00,  0 =>  2.50000E+00,  10 =>  5.51000E+00]
```

At run time, the compiler creates an empty container and populates it with elements one by one. If you define a new container type, you can specify a new `Aggregate` aspect to enable container aggregates for your container and let the compiler know what subprograms to use to construct the aggregate:

Listing 2633: main.adb

```
procedure Main is

   package JSON is
      type JSON_Value is private
        with Integer_Literal => To_JSON_Value;

      function To_JSON_Value (Text : String) return JSON_Value;

      type JSON_Array is private
        with Aggregate => (Empty       => New_JSON_Array,
                           Add_Unnamed => Append);

      function New_JSON_Array return JSON_Array;

      procedure Append
        (Self  : in out JSON_Array;
         Value : JSON_Value) is null;

   private
      type JSON_Value is null record;
      type JSON_Array is null record;

      function To_JSON_Value (Text : String) return JSON_Value
        is (null record);

      function New_JSON_Array return JSON_Array is (null record);
   end JSON;

   List : JSON.JSON_Array := [1, 2, 3];
   -------------------------------------
begin
   --  Equivalent old initialization code
   List := JSON.New_JSON_Array;
   JSON.Append (List, 1);
   JSON.Append (List, 2);
   JSON.Append (List, 3);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Container_Aggregates_2
MD5: d930702be4e6b4836afab082e8abe633
```

The equivalent for maps is:

Listing 2634: main.adb

```
procedure Main is

   package JSON is
      type JSON_Value is private
        with Integer_Literal => To_JSON_Value;

      function To_JSON_Value (Text : String) return JSON_Value;

```

(continues on next page)

(continued from previous page)

```
      type JSON_Object is private
        with Aggregate => (Empty     => New_JSON_Object,
                           Add_Named => Insert);

      function New_JSON_Object return JSON_Object;

      procedure Insert
        (Self  : in out JSON_Object;
         Key   : Wide_Wide_String;
         Value : JSON_Value) is null;

   private
      type JSON_Value is null record;
      type JSON_Object is null record;

      function To_JSON_Value (Text : String) return JSON_Value
        is (null record);

      function New_JSON_Object return JSON_Object is (null record);
   end JSON;

   Object : JSON.JSON_Object := ["a" => 1, "b" => 2, "c" => 3];
   ------------------------------------------------------------
begin
   --  Equivalent old initialization code
   Object := JSON.New_JSON_Object;
   JSON.Insert (Object, "a", 1);
   JSON.Insert (Object, "b", 2);
   JSON.Insert (Object, "c", 3);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Container_Aggregates_3
MD5: c39c651e3e2f48c515c87c4cc6b979e9
```

You can't specify both Add_Named and Add_Unnamed subprograms for the same type. This prevents you from defining JSON_Value with both array and object aggregates present. But we can define conversion functions for array and object and get code almost as dense as the same code in native JSON. For example:

Listing 2635: main.adb

```
procedure Main is

   package JSON is
      type JSON_Value is private
        with Integer_Literal => To_Value, String_Literal => To_Value;

      function To_Value (Text : String) return JSON_Value;
      function To_Value (Text : Wide_Wide_String) return JSON_Value;

      type JSON_Object is private
        with Aggregate => (Empty     => New_JSON_Object,
                           Add_Named => Insert);

      function New_JSON_Object return JSON_Object;

      procedure Insert
        (Self  : in out JSON_Object;
         Key   : Wide_Wide_String;
```

(continues on next page)

(continued from previous page)

```
         Value : JSON_Value) is null;

      function From_Object (Self : JSON_Object) return JSON_Value;

      type JSON_Array is private
        with Aggregate => (Empty       => New_JSON_Array,
                           Add_Unnamed => Append);

      function New_JSON_Array return JSON_Array;

      procedure Append
        (Self  : in out JSON_Array;
         Value : JSON_Value) is null;

      function From_Array (Self : JSON_Array) return JSON_Value;

   private
      type JSON_Value is null record;
      type JSON_Object is null record;
      type JSON_Array is null record;

      function To_Value (Text : String) return JSON_Value is
        (null record);
      function To_Value (Text : Wide_Wide_String) return JSON_Value is
        (null record);
      function New_JSON_Object return JSON_Object is
        (null record);
      function New_JSON_Array return JSON_Array is
        (null record);
      function From_Object (Self : JSON_Object) return JSON_Value is
        (null record);
      function From_Array (Self : JSON_Array) return JSON_Value is
        (null record);
   end JSON;

   function "+" (X : JSON.JSON_Object) return JSON.JSON_Value
     renames JSON.From_Object;
   function "-" (X : JSON.JSON_Array) return JSON.JSON_Value
     renames JSON.From_Array;

   Offices : JSON.JSON_Array :=
     [+["name"   => "North American Office",
        "phones" => -[1_877_787_4628,
                      1_866_787_4232,
                      1_212_620_7300],
        "email"  => "info@adacore.com"],
      +["name"   => "European Office",
        "phones" => -[33_1_49_70_67_16,
                      33_1_49_70_05_52],
        "email"  => "info@adacore.com"]];
   ------------------------------------------------------------------
begin
   --  Equivalent old initialization code is too long to print it here
   null;
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Container_Aggregates_4
MD5: a2770961eab00ee297fffa280cd9a481
```

The `Offices` variable is supposed to contain this value:

```
[{"name"  : "North American Office",
  "phones": [18777874628,
             18667874232,
             12126207300],
  "email" : "info@adacore.com"},
 {"name"  : "European Office",
  "phones": [33149706716,
             33149700552],
  "email" : "info@adacore.com"}]
```

CHAPTER

EIGHT

DELTA AGGREGATES

Note

Delta aggregates are supported by

- GNAT Community Edition 2019
- GCC 9

Sometimes you need to create a copy of an object, but with a few modifications. Before Ada 2022, doing this involves a dummy object declaration or an aggregate with associations for each property. The dummy object approach doesn't work in contract aspects or when there are limited components. On the other hand, re-listing properties in a large aggregate can be very tedious and error-prone. So, in Ada 2022, you can use a *delta aggregate* instead.

108.1 Delta aggregate for records

The delta aggregate for a record type looks like this:

```
type Vector is record
   X, Y, Z : Float;
end record;

Point_1 : constant Vector := (X => 1.0, Y => 2.0, Z => 3.0);

Projection_1 : constant Vector := (Point_1 with delta Z => 0.0);
```

The more components you have, the more you will like the delta aggregate.

108.2 Delta aggregate for arrays

You can also use delta aggregates for arrays to change elements, but not bounds. Moreover, it only works for one-dimensional arrays of non-limited components.

```
type Vector_3D is array (1 .. 3) of Float;

Point_2 : constant Vector_3D := [1.0, 2.0, 3.0];
Projection_2 : constant Vector_3D := [Point_2 with delta 3 => 0.0];
```

You can use parentheses for array aggregates, but you can't use square brackets for record aggregates.

Here is the complete code snippet:

Listing 2636: main.adb

```
with Ada.Text_IO;

procedure Main is

   type Vector is record
      X, Y, Z : Float;
   end record;

   Point_1 : constant Vector := (X => 1.0, Y => 2.0, Z => 3.0);
   Projection_1 : constant Vector := (Point_1 with delta Z => 0.0);

   type Vector_3D is array (1 .. 3) of Float;

   Point_2 : constant Vector_3D := [1.0, 2.0, 3.0];
   Projection_2 : constant Vector_3D := [Point_2 with delta 3 => 0.0];
begin
   Ada.Text_IO.Put (Float'Image (Projection_1.X));
   Ada.Text_IO.Put (Float'Image (Projection_1.Y));
   Ada.Text_IO.Put (Float'Image (Projection_1.Z));
   Ada.Text_IO.New_Line;
   Ada.Text_IO.Put (Float'Image (Projection_2 (1)));
   Ada.Text_IO.Put (Float'Image (Projection_2 (2)));
   Ada.Text_IO.Put (Float'Image (Projection_2 (3)));
   Ada.Text_IO.New_Line;
end Main;
```

CHAPTER

NINE

TARGET NAME SYMBOL (@)

Note

Target name symbol is supported by

- GNAT Community Edition 2019
- GCC 9

Ada 2022 introduces a new symbol, `@`, which can only appear on the right hand side of an assignment statement. This symbol acts as the equivalent of the name on the left hand side of that assignment statement. It was introduced to avoid code duplication: instead of retyping a (potentially long) name, you can use `@`. This symbol denotes a constant, so you can't pass it into [`in`] `out` arguments of a subprogram.

As an example, let's calculate some statistics for `My_Data` array:

Listing 2637: statistics.ads

```
package Statistics is

   type Statistic is record
      Count : Natural := 0;
      Total : Float := 0.0;
   end record;

   My_Data : array (1 .. 5) of Float := [for J in 1 .. 5 => Float (J)];

   Statistic_For_My_Data : Statistic;

end Statistics;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Assignment_Tagged_Intro
MD5: 8ca75d894ed8ddbdb459aee0ce0c427d
```

To do this, we loop over `My_Data` elements:

Listing 2638: main.adb

```
with Ada.Text_IO;

procedure Main is

   type Statistic is record
      Count : Natural := 0;
      Total : Float := 0.0;
```

(continues on next page)

(continued from previous page)

```
   end record;

   My_Data : constant array (1 .. 5) of Float :=
     [for J in 1 .. 5 => Float (J)];

   Statistic_For_My_Data : Statistic;

begin
   for Data of My_Data loop
      Statistic_For_My_Data.Count := @ + 1;
      Statistic_For_My_Data.Total := @ + Data;
   end loop;

   Ada.Text_IO.Put_Line (Statistic_For_My_Data'Image);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Assignment_Tagged_2
MD5: b116e7a172d43547b227eb27fb994366
```

Runtime output

```
(COUNT =>  5,
 TOTAL =>  1.50000E+01)
```

Each right hand side is evaluated only once, no matter how many @ symbols it contains. Let's verify this by introducing a function call that prints a line each time it's called:

Listing 2639: main.adb

```
with Ada.Text_IO;

procedure Main is

   My_Data : array (1 .. 5) of Float := [for J in 1 .. 5 => Float (J)];

   function To_Index (Value : Positive) return Positive is
   begin
      Ada.Text_IO.Put_Line ("To_Index is called.");
      return Value;
   end To_Index;

begin
   My_Data (To_Index (1)) := @ ** 2 - 3.0 * @;
   Ada.Text_IO.Put_Line (My_Data'Image);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Assignment_Tagged_3
MD5: ed946d4e1b90df28fbd358d17033279d
```

Runtime output

```
To_Index is called.

[-2.00000E+00,  2.00000E+00,  3.00000E+00,  4.00000E+00,  5.00000E+00]
```

This use of @ may look a bit cryptic, but it's the best solution that was found. Unlike other languages (e.g., `sum += x;` in C), this approach lets you use @ an arbitrary number of times

within the right hand side of an assignment statement.

109.1 Alternatives

In C++, the previous statement could be written with a reference type (one line longer!):

```
auto& a = my_data[to_index(1)];
a = a * a - 3.0 * a;
```

In Ada 2022, you can use a similar renaming:

```
declare
   A renames My_Data (To_Index (1));
begin
   A := A ** 2 - 3.0 * A;
end;
```

Here we use a new short form of the rename declaration, but this still looks too heavy, and even worse, it can't be used for discriminant-dependent components.

ENUMERATION REPRESENTATION

Note

Enumeration representation attributes are supported by

- GNAT Community Edition 2019
- GCC 9

Enumeration types in Ada are represented as integers at the machine level. But there are actually two mappings from enumeration to integer: a literal position and a representation value.

110.1 Literal positions

Each enumeration literal has a corresponding position in the type declaration. We can easily obtain it from the `Type'Pos (Enum)` attribute.

Listing 2640: main.adb

```
with Ada.Text_IO;
with Ada.Integer_Text_IO;

procedure Main is
begin
   Ada.Text_IO.Put ("Pos(False) =");
   Ada.Integer_Text_IO.Put (Boolean'Pos (False));
   Ada.Text_IO.New_Line;
   Ada.Text_IO.Put ("Pos(True)  =");
   Ada.Integer_Text_IO.Put (Boolean'Pos (True));
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Enum_Val.Pos
MD5: de7c39f83f7df231dd648606579996a8
```

Runtime output

```
Pos(False) =           0
Pos(True)  =           1
```

For the reverse mapping, we use `Type'Val (Int)`:

Listing 2641: main.adb

```
with Ada.Text_IO;

```

(continues on next page)

(continued from previous page)

```
procedure Main is
begin
   Ada.Text_IO.Put_Line (Boolean'Val (0)'Image);
   Ada.Text_IO.Put_Line (Boolean'Val (1)'Image);
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Enum_Val.Val
MD5: 43f712d25552970bccc4c0c84089d927
```

Runtime output

```
FALSE
TRUE
```

110.2 Representation values

The representation value defines the *internal* code, used to store enumeration values in memory or CPU registers. By default, enumeration representation values are the same as the corresponding literal positions, but you can redefine them. Here, we created a copy of **Boolean** type and assigned it a custom representation.

In Ada 2022, we can get an integer value of the representation with **Type**'Enum_Rep(Enum) attribute:

Listing 2642: main.adb

```
with Ada.Text_IO;
with Ada.Integer_Text_IO;

procedure Main is
   type My_Boolean is new Boolean;
   for My_Boolean use (False => 3, True => 6);
begin
   Ada.Text_IO.Put ("Enum_Rep(False) =");
   Ada.Integer_Text_IO.Put (My_Boolean'Enum_Rep (False));
   Ada.Text_IO.New_Line;
   Ada.Text_IO.Put ("Enum_Rep(True)  =");
   Ada.Integer_Text_IO.Put (My_Boolean'Enum_Rep (True));
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Enum_Val.Enum_Rep
MD5: 384ad9de7124c8131aa83ab71da58964
```

Runtime output

```
Enum_Rep(False) =          3
Enum_Rep(True)  =          6
```

And, for the reverse mapping, we can use **Type**'Enum_Val (Int):

Listing 2643: main.adb

```
with Ada.Text_IO;
with Ada.Integer_Text_IO;

```

(continues on next page)

(continued from previous page)

```
procedure Main is
   type My_Boolean is new Boolean;
   for My_Boolean use (False => 3, True => 6);
begin
   Ada.Text_IO.Put_Line (My_Boolean'Enum_Val (3)'Image);
   Ada.Text_IO.Put_Line (My_Boolean'Enum_Val (6)'Image);

   Ada.Text_IO.Put ("Pos(False) =");
   Ada.Integer_Text_IO.Put (My_Boolean'Pos (False));
   Ada.Text_IO.New_Line;
   Ada.Text_IO.Put ("Pos(True)  =");
   Ada.Integer_Text_IO.Put (My_Boolean'Pos (True));
end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Enum_Val.Enum_Val
MD5: 6e06202472d4cf0ea7c68461ac7afcb1
```

Runtime output

```
FALSE
TRUE
Pos(False) =          0
Pos(True)  =          1
```

Note that the `'Val(X)/'Pos(X)` behaviour still is the same.

Custom representations can be useful for integration with a low level protocol or hardware.

110.3 Before Ada 2022

This doesn't initially look like an important feature, but let's see how we'd do the equivalent with Ada 2012 and earlier versions. First, we need an integer type of matching size, then we instantiate `Ada.Unchecked_Conversion`. Next, we call `To_Int/From_Int` to work with representation values. And finally an extra type conversion is needed:

Listing 2644: main.adb

```
with Ada.Text_IO;
with Ada.Integer_Text_IO;
with Ada.Unchecked_Conversion;

procedure Main is

   type My_Boolean is new Boolean;
   for My_Boolean use (False => 3, True => 6);
   type My_Boolean_Int is range 3 .. 6;
   for My_Boolean_Int'Size use My_Boolean'Size;

   function To_Int is new Ada.Unchecked_Conversion
     (My_Boolean, My_Boolean_Int);

   function From_Int is new Ada.Unchecked_Conversion
     (My_Boolean_Int, My_Boolean);

begin
   Ada.Text_IO.Put ("To_Int(False) =");
   Ada.Integer_Text_IO.Put (Integer (To_Int (False)));
```

(continues on next page)

(continued from previous page)

```
21    Ada.Text_IO.New_Line;
22    Ada.Text_IO.Put ("To_Int(True)  =");
23    Ada.Integer_Text_IO.Put (Integer (To_Int (True)));
24    Ada.Text_IO.New_Line;
25    Ada.Text_IO.Put ("From_Int (3)  =");
26    Ada.Text_IO.Put_Line (From_Int (3)'Image);
27    Ada.Text_IO.New_Line;
28    Ada.Text_IO.Put ("From_Int (6)  =");
29    Ada.Text_IO.Put_Line (From_Int (6)'Image);
30 end Main;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Enum_Val.Conv
MD5: 7c7624ed024b26036389f77dbd6cb109
```

Runtime output

```
To_Int(False) =          3
To_Int(True)  =          6
From_Int (3)  =FALSE

From_Int (6)  =TRUE
```

Even with all that, this solution doesn't work for generic formal type (because T'Size must be a static value)!

We should note that these new attributes may already be familiar to GNAT users because they've been in the GNAT compiler for many years.

CHAPTER

ONE

BIG NUMBERS

Note

Big numbers are supported by

- GNAT Community Edition 2020
- GCC 11
- GCC 10 (draft, no user defined literals)

Ada 2022 introduces big integers and big real types.

111.1 Big Integers

The package `Ada.Numerics.Big_Numbers.Big_Integers` contains a type `Big_Integer` and corresponding operations such as comparison (`=`, `<`, `>`, `<=`, `>=`), arithmetic (`+`, `-`, `*`, `/`, **`rem`**, **`mod`**, **`abs`**, `**`), `Min`, `Max` and `Greatest_Common_Divisor`. The type also has `Integer_Literal` and `Put_Image` aspects redefined, so you can use it in a natural manner.

```
Ada.Text_IO.Put_Line (Big_Integer'Image(2 ** 256));
```

```
115792089237316195423570985008687907853269984665640564039457584007913129639936
```

111.2 Tiny RSA implementation

Note

Note that you shouldn't use `Big_Numbers` for cryptography because it's vulnerable to timing side-channels attacks.

We can implement the RSA algorithm[577] in a few lines of code. The main operation of RSA is (m^d) mod n. But you can't just write `m ** d`, because these are really big numbers and the result won't fit into memory. However, if you keep intermediate result **`mod`** n during the m^d calculation, it will work. Let's write this operation as a function:

[577] https://en.wikipedia.org/wiki/RSA_(cryptosystem)

Listing 2645: power_mod.ads

```
with Ada.Numerics.Big_Numbers.Big_Integers;
use  Ada.Numerics.Big_Numbers.Big_Integers;

--  Calculate M ** D mod N

function Power_Mod (M, D, N : Big_Integer) return Big_Integer;
```

Listing 2646: power_mod.adb

```
function Power_Mod (M, D, N : Big_Integer) return Big_Integer is

   function Is_Odd (X : Big_Integer) return Boolean is
     (X mod 2 /= 0);

   Result : Big_Integer := 1;
   Exp    : Big_Integer := D;
   Mult   : Big_Integer := M mod N;
begin
   while Exp /= 0 loop
      --  Loop invariant is Power_Mod'Result = Result * Mult**Exp mod N
      if Is_Odd (Exp) then
         Result := (Result * Mult) mod N;
      end if;

      Mult := Mult ** 2 mod N;
      Exp := Exp / 2;
   end loop;

   return Result;
end Power_Mod;
```

Code block metadata

```
Project: Courses.Ada_2022_Whats_New.Big_Integers
MD5: 8ade78366bf7c98090ae32f9a9830cf9
```

Let's check this with the example from Wikipedia[578]. In that example, the *public key* is (n = 3233, e = 17) and the message is m = 65. The encrypted message is m^e mod n = 65^{17} mod 3233 = 2790 = c.

```
Ada.Text_IO.Put_Line (Power_Mod (M => 65, D => 17, N => 3233)'Image);
```

```
2790
```

To decrypt it with the public key (n = 3233, d = 413), we need to calculate c^d mod n = 2790^{413} mod 3233:

```
Ada.Text_IO.Put_Line (Power_Mod (M => 2790, D => 413, N => 3233)'Image);
```

```
65
```

So 65 is the original message m. Easy!

Here is the complete code snippet:

[578] https://en.wikipedia.org/wiki/RSA_(cryptosystem)

Listing 2647: main.adb

```
with Ada.Text_IO;
with Ada.Numerics.Big_Numbers.Big_Integers;
use  Ada.Numerics.Big_Numbers.Big_Integers;

procedure Main is

   --  Calculate M ** D mod N

   function Power_Mod (M, D, N : Big_Integer) return Big_Integer is

      function Is_Odd (X : Big_Integer) return Boolean is
        (X mod 2 /= 0);

       Result : Big_Integer := 1;
       Exp    : Big_Integer := D;
       Mult   : Big_Integer := M mod N;
   begin
      while Exp /= 0 loop
         --  Loop invariant is Power_Mod'Result = Result * Mult**Exp mod N
         if Is_Odd (Exp) then
            Result := (Result * Mult) mod N;
         end if;

         Mult := Mult ** 2 mod N;
         Exp := Exp / 2;
      end loop;

      return Result;
   end Power_Mod;

begin
   Ada.Text_IO.Put_Line (Big_Integer'Image (2 ** 256));
   --  Encrypt:
   Ada.Text_IO.Put_Line (Power_Mod (M => 65, D => 17, N => 3233)'Image);
   --  Decrypt:
   Ada.Text_IO.Put_Line (Power_Mod (M => 2790, D => 413, N => 3233)'Image);
end Main;

111.3 Big Reals

In addition to Big_Integer, Ada 2022 provides Big Reals[579].

CHAPTER

TWO

INTERFACING C VARIADIC FUNCTIONS

Note

Variadic convention is supported by

- GNAT Community Edition 2020
- GCC 11

In C, variadic functions[583] take a variable number of arguments and an ellipsis as the last parameter of the declaration. A typical and well-known example is:

```
int printf (const char* format, ...);
```

Usually, in Ada, we bind such a function with just the parameters we want to use:

```
procedure printf_double
  (format : Interfaces.C.char_array;
   value  : Interfaces.C.double)
     with Import,
       Convention    => C,
       External_Name => "printf";
```

Then we call it as a normal Ada function:

```
printf_double (Interfaces.C.To_C ("Pi=%f"), Ada.Numerics.π);
```

Unfortunately, doing it this way doesn't always work because some ABI[584]s use different calling conventions for variadic functions. For example, the AMD64 ABI[585] specifies:

- `%rax` — with variable arguments passes information about the number of vector registers used;
- `%xmm0–%xmm1` — used to pass and return floating point arguments.

This means, if we write (in C):

```
printf("%d", 5);
```

The compiler will place 0 into `%rax`, because we don't pass any float argument. But in Ada, if we write:

```
procedure printf_int
  (format : Interfaces.C.char_array;
   value  : Interfaces.C.int)
```

(continues on next page)

[583] https://en.cppreference.com/w/c/variadic
[584] https://en.wikipedia.org/wiki/Application_binary_interface
[585] https://software.intel.com/sites/default/files/article/402129/mpx-linux64-abi.pdf

(continued from previous page)

```
     with Import,
       Convention    => C,
       External_Name => "printf";

printf_int (Interfaces.C.To_C ("d=%d"), 5);
```

the compiler won't use the %rax register at all. (You can't include any float argument because there's no float parameter in the Ada wrapper function declaration.) As result, you will get a crash, stack corruption, or other undefined behavior.

To fix this, Ada 2022 provides a new family of calling convention names — C_Variadic_N:

> The convention C_Variadic_n is the calling convention for a variadic C function taking *n* fixed parameters and then a variable number of additional parameters.

Therefore, the correct way to bind the printf function is:

```
procedure printf_int
  (format : Interfaces.C.char_array;
   value  : Interfaces.C.int)
     with Import,
       Convention    => C_Variadic_1,
       External_Name => "printf";
```

And the following call won't crash on any supported platform:

```
printf_int (Interfaces.C.To_C ("d=%d"), 5);
```

Without this convention, problems caused by this mismatch can be very hard to debug. So, this is a very useful extension to the Ada-to-C interfacing facility.

Here is the complete code snippet:

Listing 2648: main.adb

```
with Interfaces.C;

procedure Main is

   procedure printf_int
     (format : Interfaces.C.char_array;
      value  : Interfaces.C.int)
     with Import,
       Convention    => C_Variadic_1,
       External_Name => "printf";

begin
   printf_int (Interfaces.C.To_C ("d=%d"), 5);
end Main;
```

This book is published under a CC BY-SA license, which means that you can copy, redistribute, remix, transform, and build upon the content for any purpose, even commercially, as long as you give appropriate credit, provide a link to the license, and indicate if changes were made. If you remix, transform, or build upon the material, you must distribute your contributions under the same license as the original. You can find license details on this page[588]

This course presents an introduction to the GNAT toolchain. The course includes first steps to get started with the toolchain and some details on the project manager (GPRbuild) and the integrated development environment (GNAT Studio).

This document was written by Gustavo A. Hoffmann, with contributions and review from Richard Kenner and Robert Duff.

Note

The code examples in this course use an 80-column limit, which is a typical limit for Ada code. Note that, on devices with a small screen size, some code examples might be difficult to read.

CHAPTER

THREE

GNAT TOOLCHAIN BASICS

This chapter presents a couple of basic commands from the GNAT toolchain.

113.1 Basic commands

Now that the toolchain is installed, you can start using it. From the command line, you can compile a project using **gprbuild**. For example:

```
gprbuild -P project.gpr
```

You can find the binary built with the command above in the *obj* directory. You can then run it in the same way as you would do with any other executable on your platform. For example:

```
obj/main
```

A handy command-line option for **gprbuild** you might want to use is `-p`, which automatically creates directories such as `obj` if they aren't in the directory tree:

```
gprbuild -p -P project.gpr
```

Ada source-code is stored in *.ads* and *.adb* files. To view the content of these files, you can use **GNAT Studio**. To open **GNAT Studio**, double-click on the *.gpr* project file or invoke **GNAT Studio** on the command line:

```
gps -P project.gpr
```

To compile your project using **GNAT Studio**, use the top-level menu to invoke `Build` → `Project` → `main.adb` (or press the keyboard shortcut F4). To run the main program, click on `Build` → Run → `main` (or press the keyboard shortcut `Shift + F2`).

113.2 Compiler warnings

One of the strengths of the GNAT compiler is its ability to generate many useful warnings. Some are displayed by default but others need to be explicitly enabled. In this section, we discuss some of these warnings, their purpose, and how you activate them.

113.2.1 `-gnatwa` switch and warning suppression

Section author: Robert Duff

We first need to understand the difference between a *warning* and an *error*. Errors are violations of the Ada language rules as specified in the Ada Reference Manual; warnings don't indicate violations of those rules, but instead flag constructs in a program that seem suspicious to the compiler. Warnings are GNAT-specific, so other Ada compilers might not warn

about the same things GNAT does or might warn about them in a different way. Warnings are typically conservative; meaning that some warnings are false alarms. The programmer needs to study the code to determine if each warning is describing a real problem.

Some warnings are produced by default while others are produced only if a switch enables them. Use the `-gnatwa` switch to turn on (almost) all warnings.

Warnings are useless if you don't do anything about them. If you give your team member some code that causes warnings, how are they supposed to know whether they represent real problems? If you don't address each warning, people will soon start ignoring warnings and there'll be lots of things that generate warnings scattered all over your code. To avoid this, you may want to use the `-gnatwae` switch to both turn on (almost) all warnings and to treat warnings as errors. This forces you to get a clean (no warnings or errors) compilation.

However, as we said, some warnings are false alarms. Use **pragma** *Warnings* `(Off)` to suppress those warnings. It's best to be as specific as possible and narrow down to a single line of code and a single warning. Then use a comment to explain why the warning is a false alarm if it's not obvious.

Let's look at the following example:

```
with Ada.Text_IO; use Ada.Text_IO;

package body Warnings_Example is

   procedure Mumble (X : Integer) is
   begin
      Put_Line ("Mumble processing...");
   end Mumble;

end Warnings_Example;
```

We compile the above code with `-gnatwae`:

```
gnat compile -gnatwae ./src/warnings_example.adb
```

This causes GNAT to complain:

```
warnings_example.adb:5:22: warning: formal parameter "X" is not referenced
```

But the following compiles cleanly:

```
with Ada.Text_IO; use Ada.Text_IO;

package body Warnings_Example is

   pragma Warnings (Off, "formal parameter ""X"" is not referenced");
   procedure Mumble (X : Integer) is
   pragma Warnings (On, "formal parameter ""X"" is not referenced");

   --  X is ignored here, because blah blah blah...
   begin
      Put_Line ("Mumble processing...");
   end Mumble;

end Warnings_Example;
```

Here we've suppressed a specific warning message on a specific line.

If you get many warnings of a specific type and it's not feasible to fix all of them, you can suppress that type of message so the good warnings won't get buried beneath a pile of bogus ones. For example, you can use the `-gnatwaeF` switch to silence the warning on the first version of `Mumble` above: the `F` suppresses warnings on unreferenced formal parameters. It would be a good idea to use it if you have many of those.

As discussed above, `-gnatwa` activates almost all warnings, but not all. Refer to the section on warnings[589] of the GNAT User's Guide to get a list of the remaining warnings you could enable in your project. One is `-gnatw.o`, which displays warnings when the compiler detects modified but unreferenced **out** parameters. Consider the following example:

```
package Warnings_Example is

   procedure Process (X : in out Integer;
                      B :    out Boolean);

end Warnings_Example;
```

```
package body Warnings_Example is

   procedure Process (X : in out Integer;
                      B :    out Boolean) is
   begin
      if X = Integer'First or else X = Integer'Last then
         B := False;
      else
         X := X + 1;
         B := True;
      end if;
   end Process;

end Warnings_Example;
```

```
with Ada.Text_IO; use Ada.Text_IO;

with Warnings_Example; use Warnings_Example;

procedure Main  is
   X : Integer := 0;
   Success : Boolean;
begin
   Process (X, Success);
   Put_Line (Integer'Image (X));
end Main;
```

If we build the main application using the `-gnatw.o` switch, the compiler warns us that we didn't reference the `Success` variable, which was modified in the call to `Process`:

```
main.adb:8:16: warning: "Success" modified by call, but value might not be␣
↪referenced
```

In this case, this actually points us to a bug in our program, since X only contains a valid value if `Success` is **True**. The corrected code for `Main` is:

```
-- ...
begin
   Process (X, Success);

   if Success then
      Put_Line (Integer'Image (X));
   else
      Put_Line ("Couldn't process variable X.");
   end if;
end Main;
```

[589] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/building_executable_programs_with_gnat.html#warning-message-control

We suggest turning on as many warnings as makes sense for your project. Then, when you see a warning message, look at the code and decide if it's real. If it is, fix the code. If it's a false alarm, suppress the warning. In either case, we strongly recommend you make the warning disappear before you check your code into your configuration management system.

113.2.2 Style checking

GNAT provides many options to configure style checking of your code. The main compiler switch for this is `-gnatyy`, which sets almost all standard style check options. As indicated by the section on style checking[590] of the GNAT User's Guide, using this switch "is equivalent to `-gnaty3aAbcefhiklmnprst`, that is all checking options enabled with the exception of `-gnatyB`, `-gnatyd`, `-gnatyI`, `-gnatyLnnn`, `-gnatyo`, `-gnaty0`, `-gnatyS`, `-gnatyu`, and `-gnatyx`."

You may find that selecting the appropriate coding style is useful to detect issues at early stages. For example, the `-gnaty0` switch checks that overriding subprograms are explicitly marked as such. Using this switch can avoid surprises when you didn't intentionally want to override an operation for some data type. We recommend studying the list of coding style switches and selecting the ones that seem relevant for your project. When in doubt, you can start by using all of them — using `-gnatyy` and `-gnatyBdIL4o0Sux`, for example — and deactivating the ones that cause too much *noise* during compilation.

[590] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/building_executable_programs_with_gnat.html#style-checking

CHAPTER

FOUR

GPRBUILD

This chapter presents a brief overview of **GPRbuild**, the project manager of the GNAT toolchain. It can be used to manage complex builds. In terms of functionality, it's similar to **make** and **cmake**, just to name two examples.

For a detailed presentation of the tool, please refer to the GPRbuild User's Guide[591].

114.1 Basic commands

As mentioned in the previous chapter, you can build a project using **gprbuild** from the command line:

```
gprbuild -P project.gpr
```

In order to clean the project, you can use **gprclean**:

```
gprclean -P project.gpr
```

114.2 Project files

You can create project files using **GNAT Studio**, which presents many options on its graphical interface. However, you can also edit project files manually as a normal text file in an editor, since its syntax is human readable. In fact, project files use a syntax similar to the one from the Ada language. Let's look at the basic structure of project files and how to customize them.

114.2.1 Basic structure

The main element of a project file is a project declaration, which contains definitions for the current project. A project file may also include other project files in order to compose a complex build. One of the simplest forms of a project file is the following:

```
project Default is

   for Main use ("main");
   for Source_Dirs use ("src");

end Default;
```

In this example, we declare a project named `Default`. The `for Main use` expression indicates that the `main.adb` file is used as the entry point (main source-code file) of the project. The main file doesn't necessarily need to be called `main.adb`; we could use any source-code implementing a main application, or even have a list of multiple main files. The

[591] https://docs.adacore.com/gprbuild-docs/html/gprbuild_ug.html

`for Source_Dirs use` expression indicates that the `src` directory contains the source-file for the application (including the main file).

114.2.2 Customization

GPRbuild supports scenario variables, which allow you to control the way binaries are built. For example, you may want to distinguish between debug and optimized versions of your binary. In principle, you could pass command-line options to **gprbuild** that turn debugging on and off, for example. However, defining this information in the project file is usually easier to handle and to maintain. Let's define a scenario variable called `ver` in our project:

```
project Default is

   Ver := external ("ver", "debug");

   for Main use ("main");
   for Source_Dirs use ("src");

end Default;
```

In this example, we're specifying that the scenario variable `Ver` is initialized with the external variable `ver`. Its default value is set to `debug`.

We can now set this variable in the call to **gprbuild**:

```
gprbuild -P project.gpr -Xver=debug
```

Alternatively, we can simply specify an environment variable. For example, on Unix systems, we can say:

```
export ver=debug

# Value from environment variable "ver" used in the following call:

gprbuild -P project.gpr
```

In the project file, we can use the scenario variable to customize the build:

```
project Default is
   Ver := external ("ver", "debug");

   for Main use ("main.adb");
   for Source_Dirs use ("src");

   --  Using "ver" variable for obj directory
   for Object_Dir use "obj/" & Ver;

   package Compiler is
      case Ver is
         when "debug" =>
            for Switches ("Ada") use ("-g");
         when "opt" =>
            for Switches ("Ada") use ("-O2");
         when others =>
            null;
      end case;
   end Compiler;

end Default;
```

We're now using `Ver` in the `for Object_Dir` clause to specify a subdirectory of the `obj` directory that contains the object files. Also, we're using `Ver` to select compiler options in

the Compiler package declaration.

We could also specify all available options in the project file by creating a typed variable. For example:

```
project Default is

   type Ver_Option is ("debug", "opt");
   Ver : Ver_Option := external ("ver", "debug");

   for Source_Dirs use ("src");
   for Main use ("main.adb");

   --  Using "ver" variable for obj directory
   for Object_Dir use "obj/" & Ver;

   package Compiler is
      case Ver is
         when "debug" =>
            for Switches ("Ada") use ("-g");
         when "opt" =>
            for Switches ("Ada") use ("-O2");
         when others =>
            null;
      end case;
   end Compiler;

end Default;
```

The advantage of this approach is that **gprbuild** can now check whether the value that you provide for the ver variable is available on the list of possible values and give you an error if you're entering a wrong value.

114.3 Project dependencies

GPRbuild supports project dependencies. This allows you to reuse information from existing projects. Specifically, the keyword **with** allows you to include another project within the current project.

114.3.1 Simple dependency

Let's look at a very simple example. We have a package called Test_Pkg associated with the project file test_pkg.gpr, which contains:

```
project Test_Pkg is
    for Source_Dirs use ("src");
    for Object_Dir use "obj";
end Test_Pkg;
```

This is the code for the Test_Pkg package:

```
package Test_Pkg is

   type T is record
      X : Integer;
      Y : Integer;
   end record;

   function Init return T;
```

(continues on next page)

(continued from previous page)

```
end Test_Pkg;
```

```
package body Test_Pkg is

   function Init return T is
   begin
      return V : T do
         V.X := 0;
         V.Y := 0;
      end return;
   end Init;

end Test_Pkg;
```

For this example, we use a directory `test_pkg` containing the project file and a subdirectory `test_pkg/src` containing the source files. The directory structure looks like this:

```
|- test_pkg
|    | test_pkg.gpr
|    |- src
|    |    | test_pkg.adb
|    |    | test_pkg.ads
```

Suppose we want to use the `Test_Pkg` package in a new application. Instead of directly including the source files of `Test_Pkg` in the project file of our application (either directly or indirectly), we can instead reference the existing project file for the package by using `with "test_pkg.gpr"`. This is the resulting project file:

```
with "../test_pkg/test_pkg.gpr";

project Default is
    for Source_Dirs use ("src");
    for Object_Dir use "obj";
    for Main use ("main.adb");
end Default;
```

And this is the code for the main application:

```
with Test_Pkg; use Test_Pkg;

procedure Main is
   A : T;
begin
   A := Init;
end Main;
```

When we build the main project file (`default.gpr`), we're automatically building all dependent projects. More specifically, the project file for the main application automatically includes the information from the dependent projects such as `test_pkg.gpr`. Using a `with` in the main project file is all we have to do for that to happen.

114.3.2 Dependencies to dynamic libraries

We can structure project files to make use of dynamic (shared) libraries using a very similar approach. It's straightforward to convert the project above so that `Test_Pkg` is now compiled into a dynamic library and linked to our main application. All we need to do is to make a few additions to the project file for the `Test_Pkg` package:

```
library project Test_Pkg is
    for Source_Dirs use ("src");
    for Object_Dir use "obj";
    for Library_Name use "test_pkg";
    for Library_Dir use "lib";
    for Library_Kind use "Dynamic";
end Test_Pkg;
```

This is what we had to do:

- We changed the `project` to `library project`.
- We added the specification for `Library_Name`, `Library_Dir` and `Library_Kind`.

We don't need to change the project file for the main application because **GPRbuild** automatically detects the dependency information (e.g., the path to the dynamic library) from the project file for the `Test_Pkg` package. With these small changes, we're able to compile the `Test_Pkg` package to a dynamic library and link it with our main application.

114.4 Configuration pragma files

Configuration pragma files contain a set of pragmas that modify the compilation of source files according to external requirements. For example, you may use pragmas to either relax or strengthen requirements depending on your environment.

In **GPRbuild**, we can use `Local_Configuration_Pragmas` (in the `Compiler` package) to indicate the configuration pragmas file we want **GPRbuild** to use with the source files in our project.

The file `gnat.adc` shown here is an example of a configuration pragma file:

```
pragma Suppress (Overflow_Check);
```

We can use this in our project by declaring a `Compiler` package. Here's the complete project file:

```
project Default is

   for Source_Dirs use ("src");
   for Object_Dir use "obj";
   for Main use ("main.adb");

   package Compiler is
      for Local_Configuration_Pragmas use "gnat.adc";
   end Compiler;

end Default;
```

Each pragma contained in `gnat.adc` is used in the compilation of each file, as if that pragma was placed at the beginning of each file.

114.5 Configuration packages

You can control the compilation of your source code by creating variants for various cases and selecting the appropriate variant in the compilation package in the project file. One example where this is useful is conditional compilation using Boolean constants, shown in the code below:

```
with Ada.Text_IO; use Ada.Text_IO;

with Config;

procedure Main is
begin

   if Config.Debug then
      Put_Line ("Debug version");
   else
      Put_Line ("Release version");
   end if;
end Main;
```

In this example, we declared the Boolean constant in the `Config` package. By having multiple versions of that package, we can create different behavior for each usage. For this simple example, there are only two possible cases: either Debug is **`True`** or **`False`**. However, we can apply this strategy to create more complex cases.

In our next example, we store the packages in the subdirectories debug and `release` of the source code directory. Here's the content of the `src/debug/config.ads` file:

```
package Config is

   Debug : constant Boolean := True;

end Config;
```

Here's the `src/release/config.ads` file:

```
package Config is

   Debug : constant Boolean := False;

end Config;
```

In this case, **`GPRbuild`** selects the appropriate directory to look for the `config.ads` file according to information we provide for the compilation process. We do this by using a scenario type called Mode_Type in our project file:

```
gprbuild -P default.gpr -Xmode=release
```

```
project Default is

   type Mode_Type is ("debug", "release");

   Mode : Mode_Type := external ("mode", "debug");

   for Source_Dirs use ("src", "src/" & Mode);
   for Object_Dir use "obj";
   for Main use ("main.adb");

end Default;
```

We declare the scenario variable Mode and use it in the `Source_Dirs` declaration to add the desired path to the subdirectory containing the `config.ads` file. The expression `"src/" &` Mode concatenates the user-specified mode to select the appropriate subdirectory. For more complex cases, we could use either a tree of subdirectories or multiple scenario variables for each aspect that we need to configure.

CHAPTER

FIVE

GNAT STUDIO

This chapter presents an introduction to the GNAT Studio, which provides an IDE to develop applications in Ada. For a detailed overview, please refer to the GNAT Studio tutorial[592]. Also, you can refer to the GNAT Studio product page[593] for some introductory videos.

In this chapter, all indications using "→" refer to options from the GNAT Studio menu that you can click in order to execute commands.

115.1 Start-up

The first step is to start-up the GNAT Studio. The actual step depends on your platform.

115.1.1 Windows

- You may find an icon (shortcut to **`GNAT Studio`**) on your desktop.
- Otherwise, start **`GNAT Studio`** by typing `gnatstudio` on the command prompt.

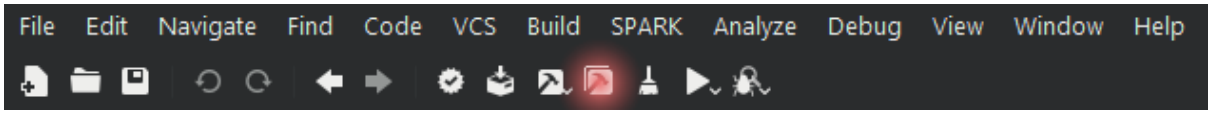
115.1.2 Linux

- Start **`GNAT Studio`** by typing `gnatstudio` on a shell.

115.2 Creating projects

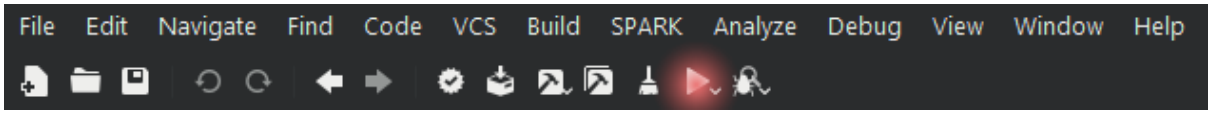
After starting-up **`GNAT Studio`**, you can create a project. These are the steps:

- Click on `Create new project` in the welcome window
  - Alternatively, if the *wizard* (which let's you customize new projects) isn't already opened, click on `File` → `New Project...` to open it.
  - After clicking on `Create new project`, you should see a window with this title: `Create Project from Template`.
- Select one of the options from the list and click on `Next`.
  - The simplest one is `Basic > Simple Ada Project`, which creates a project containing a main application.
- Select the project location and basic settings, and click on `Apply`.
  - If you selected "Simple Ada Project" in the previous step, you may now select the name of the project and of the main file.
  - Note that you can select any name for the main file.



[592] https://docs.adacore.com/live/wave/gps/html/gps_tutorial/index.html
[593] https://www.adacore.com/gnatpro/toolsuite/gps

You should now have a working project file.

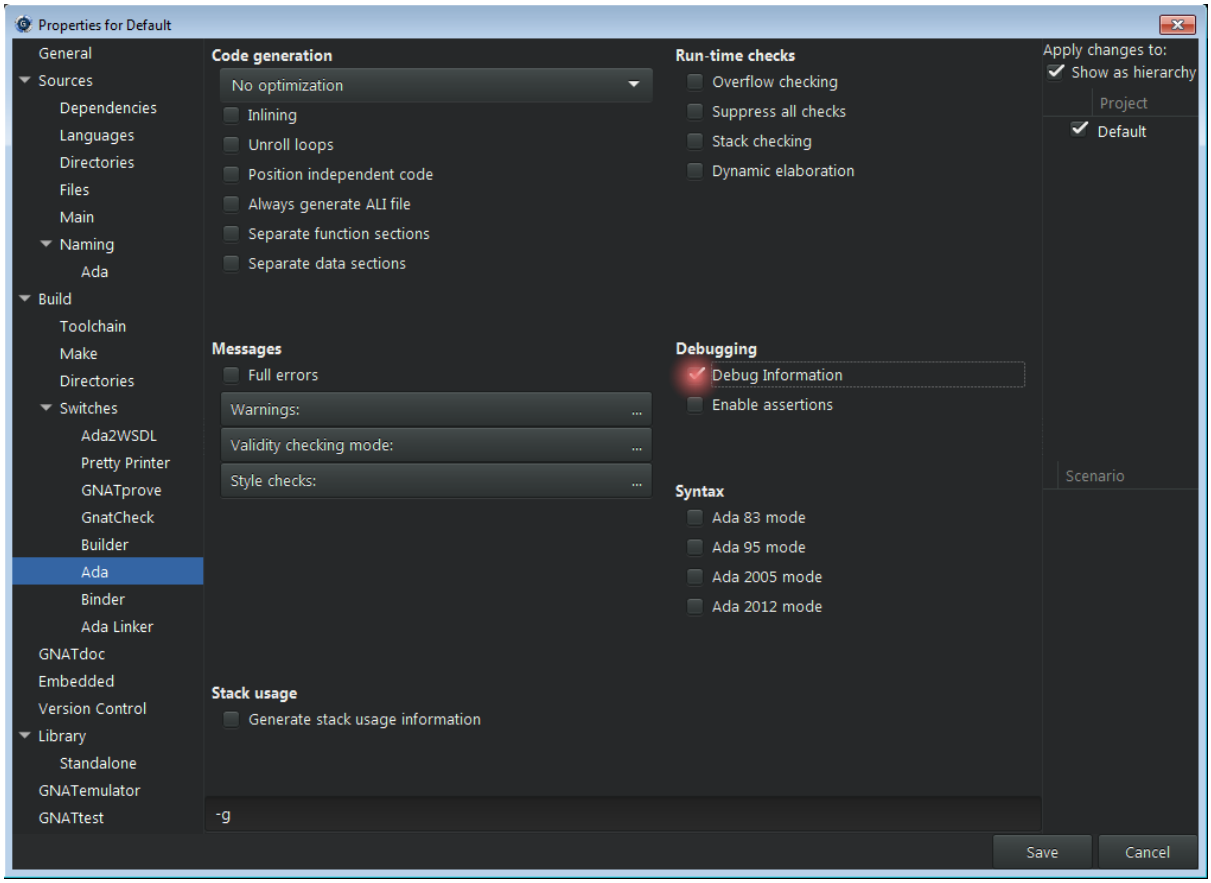


115.3 Building

As soon as you've created a project file, you can use it to build an application. These are the required steps:

- Click on `Build` → `Project` → `Build All`
  - You can also click on this icon:

- Alternatively, you can click on `Build` → `Project` → `Build & Run` → `<name of your main application>`
  - You can also click on this icon:



- You can also use the keyboard for building and running the main application:
  - Press F4 to open a window that allows you to build the main application and click on Execute.
  - Then, press `Shift + F2` to open a window that allows you to run the application, and click on Execute.

115.4 Debugging

115.4.1 Debug information

Before you can debug a project, you need to make sure that debugging symbols have been included in the binary build. You can do this by manually adding a debug version into your project, as described in the previous chapter (see *GPRbuild* (page 2289)).

Alternatively, you can change the project properties directly in **`GNAT Studio`**. In order to do that, click on `Edit` → `Project Properties...`, which opens the following window:

Click on `Build` → `Switches` → `Ada` on this window, and make sure that the `Debug Information` option is selected.

115.4.2 Improving main application

If you selected "Simple Ada Project" while creating your project in the beginning, you probably still have a very simple main application that doesn't do anything useful. Therefore, in order to make the debugging activity more interesting, please enter some statements to your application. For example:

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
begin
   Put_Line ("Hello World!");
   Put_Line ("Hello again!");
end Main;
```

115.4.3 Debugging the application

You can now build and debug the application by clicking on `Build` → `Project` → `Build & Debug` → `<name of your main application>`.

You can then click on `Debug` → `Run...` to open a window that allows you to start the application. Alternatively, you can press `Shift + F9`. As soon as the application has started, you can press F5 to step through the application or press F6 to execute until the next line. Both commands are available in the menu by clicking on `Debug` → `Step` or `Debug` → `Next`.

When you've finished debugging your application, you need to terminate the debugger. To do this, you can click on `Debug` → `Terminate`.

115.5 Formal verification

In order to see how SPARK can detect issues, let's create a simple application that accumulates values in a variable A:

```
procedure Main
  with SPARK_Mode is

   procedure Acc (A : in out Natural;
                  V :        Natural) is
   begin
      A := A + V;
   end Acc;

   A : Natural := 0;
begin
   Acc (A, Natural'Last);
   Acc (A, 1);
end Main;
```

You can now click on SPARK → `Prove All`, which opens a window with various options. For example, on this window, you can select the proof level — varying between 0 and 4 — on the `Proof level` list. Next, click on `Execute`. After the prover has completed its analysis, you'll see a list of issues found in the source code of your application.

For the example above, the prover complains about an overflow check that might fail. This is due to the fact that, in the Acc procedure, we're not dealing with the possibility that the result of the addition might be out of range. In order to fix this, we could define a new saturating addition Sat_Add that makes use of a custom type T with an extended range. For example:

```
procedure Main
  with SPARK_Mode is

   function Sat_Add (A : Natural;
                     V : Natural) return Natural
   is
      type T is range Natural'First .. Natural'Last * 2;

      A2     : T          := T (A);
      V2     : constant T := T (V);
      A_Last : constant T := T (Natural'Last);
   begin
      A2 := A2 + V2;

      --  Saturate result if needed
      if A2 > A_Last then
         A2 := A_Last;
      end if;

      return Natural (A2);
   end Sat_Add;

   procedure Acc (A : in out Natural;
                  V :        Natural) is
   begin
      A := Sat_Add (A, V);
   end Acc;

   A : Natural := 0;
begin
   Acc (A, Natural'Last);
```

(continues on next page)

(continued from previous page)

```
   Acc (A, 1);
end Main;
```

Now, when running the prover again with the modified code, no issues are found.

CHAPTER

SIX

GNAT TOOLS

In this chapter we present a brief overview of some of the tools included in the GNAT toolchain.

For further details on how to use these tools, please refer to the GNAT User's Guide[594].

116.1 gnatchop

gnatchop renames files so they match the file structure and naming convention expected by the rest of the GNAT toolchain. The GNAT compiler expects specifications to be stored in `.ads` files and bodies (implementations) to be stored in `.adb` files. It also expects file names to correspond to the content of each file. For example, it expects the specification of a package `Pkg.Child` to be stored in a file named `pkg-child.ads`.

However, we may not want to use that convention for our project. For example, we may have multiple Ada packages contained in a single file. Consider a file `example.ada` containing the following:

```
with Ada.Text_IO; use Ada.Text_IO;

package P is
   procedure Test;
end P;

package body P is
   procedure Test is
   begin
      Put_Line("Test passed.");
   end Test;
end P;

with P; use P;

procedure P_Main is
begin
   P.Test;
end P_Main;
```

To compile this code, we first pass the file containing our source code to **gnatchop** before we call **gprbuild**:

```
gnatchop example.ada
gprbuild p_main
```

This generates source files for our project, extracted from `example_ada`, that conform to the default naming convention and then builds the executable binary `p_main` from those

[594] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn.html

files. In this example **gnatchop** created the files `p.ads`, `p.adb`, and `p_main.adb` using the package names in `example.ada`.

When we use this mechanism, any warnings or errors the compiler displays refers to the files generated by **gnatchop**. We can, however, instruct **gnatchop** to instrument the generated files so the compiler refers to the original file (`example.ada` in our case) when displaying messages. We do this by using the `-r` switch:

```
gnatchop -r example.ada
gprbuild p_main
```

If, for example, we had an unused variable in `example.ada`, the compiler warning would now refer to the line in the original file, not in one of the generated ones.

For documentation of other switches available for **gnatchop**, please refer to the gnatchop chapter[595] of the GNAT User's Guide.

116.2 gnatprep

We may want to use conditional compilation in some situations. For example, we might need a customized implementation of a package for a specific platform or need to select a specific version of an algorithm depending on the requirements of the target environment. A traditional way to do this uses a source-code preprocessor. However, in many cases where conditional compilation is needed, we can instead use the syntax of the Ada language or the functionality provided by **GPRbuild** to avoid using a preprocessor in those cases. The conditional compilation section[596] of the GNAT User's Guide discusses how to do this in detail.

Nevertheless, using a preprocessor is often the most straightforward option in complex cases. When we encounter such a case, we can use **gnatprep**, which provides a syntax that reminds us of the C and C++ preprocessor. However, unlike in C and C++, this syntax is not part of the Ada standard and can only be used with **gnatprep**. Also, you'll notice some differences in the syntax from that preprocessor, such as shown in the example below:

```
#if VERSION'Defined and then (VERSION >= 4) then
   --  Implementation for version 4.0 and above...
#else
   --  Standard implementation for older versions...
#end if;
```

Of course, in this simple case, we could have used the Ada language directly and avoided the preprocessor entirely:

```
package Config is
   Version : constant Integer := 4;
end Config;

with Config;
procedure Do_Something is
begin
   if Config.Version >= 4 then
      null;
      --  Implementation for version 4.0 and above...
   else
      null;
      --  Standard implementation for older versions...
```

(continues on next page)

[595] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/the_gnat_compilation_model.html#renaming-files-with-gnatchop
[596] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/the_gnat_compilation_model.html#conditional-compilation

(continued from previous page)

```
   end if;
end Do_Something;
```

But for the sake of illustrating the use of **gnatprep**, let's use that tool in this simple case. This is the complete procedure, which we place in file `do_something.org.adb`:

```
procedure Do_Something is
begin
   #if VERSION'Defined and then (VERSION >= 4) then
   --  Implementation for version 4.0 and above...
   null;
   #else
   --  Standard implementation for older versions...
   null;
   #end if;
end Do_Something;
```

To preprocess this file and build the application, we call **gnatprep** followed by **GPRbuild**:

```
gnatprep do_something.org.adb do_something.adb
gprbuild do_something
```

If we look at the resulting file after preprocessing, we see that the `#else` implementation was selected by **gnatprep**. To cause it to select the newer "version" of the code, we include the symbol and its value in our call to **gnatprep**, just like we'd do for C/C++:

```
gnatprep -DVERSION=5 do_something.org.adb do_something.adb
```

However, a cleaner approach is to create a symbol definition file containing all symbols we use in our implementation. Let's create the file and name it `prep.def`:

```
VERSION := 5
```

Now we just need to pass it to **gnatprep**:

```
gnatprep do_something.org.adb do_something.adb prep.def
gprbuild do_something
```

When we use **gnatprep** in that way, the line numbers of the output file differ from those of the input file. To preserve line numbers, we can use one of these command-line switches:

- `-b`: replace stripped-out code by blank lines
- `-c`: comment-out the stripped-out code

For example:

```
gnatprep -b do_something.org.adb do_something.adb prep.def
gnatprep -c do_something.org.adb do_something.adb prep.def
```

When we use one of these options, **gnatprep** ensures that the output file `do_something.adb` has the same line numbering as the original file (`do_something.org.adb`).

The gnatprep chapter[597] of the GNAT User's Guide contains further details about this tool, such as how to integrate **gnatprep** with project files for **GPRbuild** and how to replace symbols without using preprocessing directives (using the `$symbol` syntax).

[597] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/the_gnat_compilation_model.html#preprocessing-with-gnatprep

116.3 gnatmem

Memory allocation errors involving mismatches between allocations and deallocations are a common source of memory leaks. To test an application for memory allocation issues, we can use **gnatmem**. This tool monitors all memory allocations in our application. We use this tool by linking our application to a special version of the memory allocation library (`libgmem.a`).

Let's consider this simple example:

```
procedure Simple_Mem is
   I_Ptr : access Integer := new Integer;
begin
   null;
end Simple_Mem;
```

To generate a memory report for this code, we need to:

- Build the application, linking it to `libgmem.a`;
- Run the application, which generates an output file (`gmem.out`);
- Run **gnatmem** to generate a report from `gmem.out`.

For our example above, we do the following:

```
# Build application using gmem
gnatmake -g simple_mem.adb -largs -lgmem

# Run the application and generate gmem.out
./simple_mem

# Call gnatmem to display the memory report based on gmem.out
gnatmem simple_mem
```

For this example, **gnatmem** produces the following output:

```
Global information
------------------
   Total number of allocations        :   1
   Total number of deallocations      :   0
   Final Water Mark (non freed mem)   : 4 Bytes
   High Water Mark                    : 4 Bytes

Allocation Root # 1
-------------------
 Number of non freed allocations    :   1
 Final Water Mark (non freed mem)   : 4 Bytes
 High Water Mark                    : 4 Bytes
 Backtrace                          :
   simple_mem.adb:2 simple_mem
```

This shows all the memory we allocated and tells us that we didn't deallocate any of it.

Please refer to the chapter on gnatmem[598] of the GNAT User's Guide for a more detailed discussion of **gnatmem**.

[598] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/gnat_and_program_execution.html#the-gnatmem-tool

116.4 gnatdoc

Use **GNATdoc** to generate HTML documentation for your project. It scans the source files in the project and extracts information from package, subprogram, and type declarations.

The simplest way to use it is to provide the name of the project or to invoke **GNATdoc** from a directory containing a project file:

```
gnatdoc -P some_directory/default.gpr

# Alternatively, when the :file:`default.gpr` file is in the same directory

gnatdoc
```

Just using this command is sufficient if your goal is to generate a list of the packages and a list of subprograms in each. However, to create more meaningful documentation, you can annotate your source code to add a description of each subprogram, parameter, and field. For example:

```
package P is
--  Collection of auxiliary subprograms

   function Add_One
     (V : Integer
      --  Coefficient to be incremented
     ) return Integer;
   --  @return Coefficient incremented by one

end P;
```

```
package body P is

   function Add_One (V : Integer) return Integer is
   begin
      return V + 1;
   end Add_One;

end P;
```

```
with P; use P;

procedure Main is

   I : Integer;

begin
   I := Add_One (0);
end Main;
```

When we run this example, **GNATdoc** will extract the documentation from the specification of package P and add the description of each element, which we provided as a comment in the line below the actual declaration. It will also extract the package description, which we wrote as a comment in the line right after `package P is`. Finally, it will extract the documentation of function Add_One (both the description of the V parameter and the return value).

In addition to the approach we've just seen, **GNATdoc** also supports the tagged format that's commonly found in tools such as Javadoc and uses the @ syntax. We could rewrite the documentation for package P as follows:

```
package P is
-- @summary Collection of auxiliary subprograms

   function Add_One
     (V : Integer
     ) return Integer;
   -- @param V Coefficient to be incremented
   -- @return Coefficient incremented by one

end P;
```

You can control what parts of the source-code **GNATdoc** parses to extract the documentation. For example, you can specify the `-b` switch to request that the package body be parsed for additional documentation and you can use the `-p` switch to request **GNATdoc** to parse the private part of package specifications. For a complete list of switches, please refer to the GNATdoc User's Guide[599].

116.5 gnatpp

The term 'pretty-printing' refers to the process of formatting source code according to a pre-defined convention. **gnatpp** is used for the pretty-printing of Ada source-code files.

Let's look at this example, which contains very messy formatting:

```
PrOcEDuRE Main
                  IS

   FUNCtioN
                         Init_2
                  RETurn
     inteGER                iS
                                    (2);

               I : INTeger;

     BeGiN
            I             :=        Init_2;
                 ENd;
```

We can request **gnatpp** to clean up this file by using the command:

```
gnatpp main.adb
```

gnatpp reformats the file in place. After this command, `main.adb` looks like this:

```
procedure Main is

   function Init_2 return Integer is (2);

   I : Integer;

begin
   I := Init_2;
end Main;
```

[599] http://docs.adacore.com/gnatdoc-docs/users_guide/_build/html/index.html

We can also process all source code files from a project at once by specifying a project file. For example:

```
gnatpp -P default.gpr
```

gnatpp has an extensive list of options, which allow for specifying the formatting of many aspects of the source and implementing many coding styles. These are extensively discussed in the section on gnatpp[600] of the GNAT User's Guide.

116.6 gnatstub

Suppose you've created a complex specification of an Ada package. You can create the corresponding package body by copying and adapting the content of the package specification. But you can also have **gnatstub** do much of that job for you. For example, let's consider the following package specification:

```
package Aux is

   function Add_One (V : Integer) return Integer;

   procedure Reset (V : in out Integer);

end Aux;
```

We call **gnatstub**, passing the file containing the package specification:

```
gnatstub aux.ads
```

This generates the file aux.adb with the following contents:

```
pragma Ada_2012;
package body Aux is

   -------------
   -- Add_One --
   -------------

   function Add_One (V : Integer) return Integer is
   begin
      --  Generated stub: replace with real body!
      pragma Compile_Time_Warning (Standard.True, "Add_One unimplemented");
      return raise Program_Error with "Unimplemented function Add_One";
   end Add_One;

   -----------
   -- Reset --
   -----------

   procedure Reset (V : in out Integer) is
   begin
      --  Generated stub: replace with real body!
      pragma Compile_Time_Warning (Standard.True, "Reset unimplemented");
      raise Program_Error with "Unimplemented procedure Reset";
   end Reset;

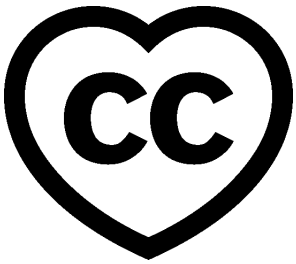
end Aux;
```

As we can see in this example, not only has **gnatstub** created a package body from all the elements in the package specification, but it also created:

[600] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/gnat_utility_programs.html#the-gnat-pretty-printer-gnatpp

- Headers for each subprogram (as comments);
- Pragmas and exceptions that prevent us from using the unimplemented subprograms in our application.

This is a good starting point for the implementation of the body. Please refer to the section on gnatstub[601] of the GNAT User's Guide for a detailed discussion of **gnatstub** and its options.



[601] https://docs.adacore.com/gnat_ugn-docs/html/gnat_ugn/gnat_ugn/gnat_utility_programs.html#the-body-stub-generator-gnatstub

Part XII

Introduction to Ada: Laboratories

Copyright © 2019 – 2024, AdaCore

This book is published under a CC BY-SA license, which means that you can copy, redistribute, remix, transform, and build upon the content for any purpose, even commercially, as long as you give appropriate credit, provide a link to the license, and indicate if changes were made. If you remix, transform, or build upon the material, you must distribute your contributions under the same license as the original. You can find license details on this page[602]

These labs contain exercises for the *Introduction to Ada* (page 5) course.

This document was written by Gustavo A. Hoffmann and reviewed by Michael Frank.

Note

The code examples in this course use an 80-column limit, which is a typical limit for Ada code. Note that, on devices with a small screen size, some code examples might be difficult to read.

CHAPTER

SEVEN

IMPERATIVE LANGUAGE

For the exercises below (except for the first one), don't worry about the details of the `Main` procedure. You should just focus on implementing the application in the subprogram specified by the exercise.

117.1 Hello World

Goal: create a "Hello World!" application.

Steps:

1. Complete the `Main` procedure.

Requirements:

1. The application must display the message "Hello World!".

Remarks:

1. The part that you have to modify is indicated by the *`-- Implement the application here!`* comment in the source code.

Listing 2649: main.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
begin
   --  Implement the application here!
   null;
end Main;
```

117.2 Greetings

Goal: create an application that greets a person.

Steps:

1. Complete the `Greet` procedure.

Requirements:

1. Given an input string <name>, procedure `Greet` must display the message "Hello <name>!".
    1. For example, if the name is "John", it displays the message "Hello John!".

Remarks:

1. You can use the concatenation operator (`&`).

2. The part that you have to modify is indicated by the `-- Implement the application here!` comment in the source code.

Listing 2650: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

procedure Main is

   procedure Greet (Name : String) is
   begin
      --  Implement the application here!
      null;
   end Greet;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Greet (Argument (1));
end Main;
```

117.3 Positive Or Negative

Goal: create an application that classifies integer numbers.

Steps:

1. Complete the `Classify_Number` procedure.

Requirements:

1. Given an integer number `X`, procedure `Classify_Number` must classify `X` as positive, negative or zero and display the result:
    1. If `X > 0`, it displays `Positive`.
    2. If `X < 0`, it displays `Negative`.
    3. If `X = 0`, it displays `Zero`.

Listing 2651: classify_number.ads

```
procedure Classify_Number (X : Integer);
```

Listing 2652: classify_number.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Classify_Number (X : Integer) is
begin
   --  Implement the application here!
   null;
end Classify_Number;
```

Listing 2653: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Classify_Number;

procedure Main is
   A : Integer;
begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   A := Integer'Value (Argument (1));

   Classify_Number (A);
end Main;
```

117.4 Numbers

Goal: create an application that displays numbers in a specific order.

Steps:

1. Complete the `Display_Numbers` procedure.

Requirements:

1. Given two integer numbers, `Display_Numbers` displays all numbers in the range starting with the smallest number.

Listing 2654: display_numbers.ads

```
procedure Display_Numbers (A, B : Integer);
```

Listing 2655: display_numbers.adb

```
procedure Display_Numbers (A, B : Integer) is
begin
   --  Implement the application here!
   null;
end Display_Numbers;
```

Listing 2656: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Display_Numbers;

procedure Main is
   A, B : Integer;
begin
   if Argument_Count < 2 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
```

(continues on next page)

(continued from previous page)

```
   elsif Argument_Count > 2 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   A := Integer'Value (Argument (1));
   B := Integer'Value (Argument (2));

   Display_Numbers (A, B);
end Main;
```

CHAPTER

EIGHT

SUBPROGRAMS

118.1 Subtract procedure

Goal: write a procedure that subtracts two numbers.

Steps:

1. Complete the procedure `Subtract`.

Requirements:

1. `Subtract` performs the operation `A - B`.

Listing 2657: subtract.ads

```
--  Write the correct parameters for the procedure below.
procedure Subtract;
```

Listing 2658: subtract.adb

```
procedure Subtract is
begin
   --  Implement the procedure here.
   null;
end Subtract;
```

Listing 2659: main.adb

```
with Ada.Command_Line;     use Ada.Command_Line;
with Ada.Text_IO;          use Ada.Text_IO;

with Subtract;

procedure Main is
   type Test_Case_Index is
     (Sub_10_1_Chk,
      Sub_10_100_Chk,
      Sub_0_5_Chk,
      Sub_0_Minus_5_Chk);

   procedure Check (TC : Test_Case_Index) is
      Result : Integer;
   begin
      case TC is
      when Sub_10_1_Chk =>
         Subtract (10, 1, Result);
         Put_Line ("Result: " & Integer'Image (Result));
      when Sub_10_100_Chk =>
         Subtract (10, 100, Result);
```

(continues on next page)

(continued from previous page)

```
         Put_Line ("Result: " & Integer'Image (Result));
      when Sub_0_5_Chk =>
         Subtract (0, 5, Result);
         Put_Line ("Result: " & Integer'Image (Result));
      when Sub_0_Minus_5_Chk =>
         Subtract (0, -5, Result);
         Put_Line ("Result: " & Integer'Image (Result));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

118.2 Subtract function

Goal: write a function that subtracts two numbers.

Steps:

1. Rewrite the `Subtract` procedure from the previous exercise as a function.

Requirements:

1. `Subtract` performs the operation `A - B` and returns the result.

Listing 2660: subtract.ads

```
--  Write the correct signature for the function below.
--  Don't forget to replace the keyword "procedure" by "function."
procedure Subtract;
```

Listing 2661: subtract.adb

```
procedure Subtract is
begin
   --  Implement the function here!
   null;
end Subtract;
```

Listing 2662: main.adb

```
with Ada.Command_Line;     use Ada.Command_Line;
with Ada.Text_IO;          use Ada.Text_IO;

with Subtract;

procedure Main is
   type Test_Case_Index is
     (Sub_10_1_Chk,
      Sub_10_100_Chk,
      Sub_0_5_Chk,
      Sub_0_Minus_5_Chk);
```

(continues on next page)

(continued from previous page)

```
12
13    procedure Check (TC : Test_Case_Index) is
14       Result : Integer;
15    begin
16       case TC is
17       when Sub_10_1_Chk =>
18          Result := Subtract (10, 1);
19          Put_Line ("Result: " & Integer'Image (Result));
20       when Sub_10_100_Chk =>
21          Result := Subtract (10, 100);
22          Put_Line ("Result: " & Integer'Image (Result));
23       when Sub_0_5_Chk =>
24          Result := Subtract (0, 5);
25          Put_Line ("Result: " & Integer'Image (Result));
26       when Sub_0_Minus_5_Chk =>
27          Result := Subtract (0, -5);
28          Put_Line ("Result: " & Integer'Image (Result));
29       end case;
30    end Check;
31
32 begin
33    if Argument_Count < 1 then
34       Put_Line ("ERROR: missing arguments! Exiting...");
35       return;
36    elsif Argument_Count > 1 then
37       Put_Line ("Ignoring additional arguments...");
38    end if;
39
40    Check (Test_Case_Index'Value (Argument (1)));
41 end Main;
```

118.3 Equality function

Goal: write a function that compares two values and returns a flag.

Steps:

1. Complete the `Is_Equal` subprogram.

Requirements:

1. `Is_Equal` returns a flag as a **`Boolean`** value.
2. The flag must indicate whether the values are equal (flag is **`True`**) or not (flag is **`False`**).

Listing 2663: is_equal.ads

```
1 --  Write the correct signature for the function below.
2 --  Don't forget to replace the keyword "procedure" by "function."
3 procedure Is_Equal;
```

Listing 2664: is_equal.adb

```
1 procedure Is_Equal is
2 begin
3    --  Implement the function here!
4    null;
5 end Is_Equal;
```

Listing 2665: main.adb

```
with Ada.Command_Line;     use Ada.Command_Line;
with Ada.Text_IO;          use Ada.Text_IO;

with Is_Equal;

procedure Main is
   type Test_Case_Index is
     (Equal_Chk,
      Inequal_Chk);

   procedure Check (TC : Test_Case_Index) is

      procedure Display_Equal (A, B  : Integer;
                               Equal : Boolean) is
      begin
         Put (Integer'Image (A));
         if Equal then
            Put (" is equal to ");
         else
            Put (" isn't equal to ");
         end if;
         Put_Line (Integer'Image (B) & ".");
      end Display_Equal;

      Result : Boolean;
   begin
      case TC is
      when Equal_Chk =>
         for I in 0 .. 10 loop
            Result := Is_Equal (I, I);
            Display_Equal (I, I, Result);
         end loop;
      when Inequal_Chk =>
         for I in 0 .. 10 loop
            Result := Is_Equal (I, I - 1);
            Display_Equal (I, I - 1, Result);
         end loop;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

118.4 States

Goal: write a procedure that displays the state of a machine.

Steps:

1. Complete the procedure `Display_State`.

Requirements:

1. The states can be set according to the following numbers:

Number	State
0	Off
1	On: Simple Processing
2	On: Advanced Processing

2. The procedure `Display_State` receives the number corresponding to a state and displays the state (indicated by the table above) as a user message.

Remarks:

1. You can use a case statement to implement this procedure.

Listing 2666: display_state.ads

```
procedure Display_State (State : Integer);
```

Listing 2667: display_state.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Display_State (State : Integer) is
begin
   null;
end Display_State;
```

Listing 2668: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Display_State;

procedure Main is
   State : Integer;
begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   State := Integer'Value (Argument (1));

   Display_State (State);
end Main;
```

118.5 States #2

Goal: write a function that returns the state of a machine.

Steps:

1. Implement the function `Get_State`.

Requirements:

1. Implement same state machine as in the previous exercise.
2. Function `Get_State` must return the state as a string.

Remarks:

1. You can implement a function returning a string by simply using quotes in a return statement. For example:

Listing 2669: get_hello.ads

```
function Get_Hello return String;
```

Listing 2670: get_hello.adb

```
function Get_Hello return String is
begin
   return "Hello";
end Get_Hello;
```

Listing 2671: main.adb

```
with Ada.Text_IO;      use Ada.Text_IO;
with Get_Hello;

procedure Main is
   S : constant String := Get_Hello;
begin
   Put_Line (S);
end Main;
```

2. You can reuse your previous implementation and replace it by a case expression.
    1. For values that do not correspond to a state, you can simply return an empty string ("").

Listing 2672: get_state.ads

```
function Get_State (State : Integer) return String;
```

Listing 2673: get_state.adb

```
function Get_State (State : Integer) return String is
begin
   return "";
end Get_State;
```

Listing 2674: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Get_State;

procedure Main is
   State : Integer;
begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
```

(continues on next page)

(continued from previous page)

```
   end if;

   State := Integer'Value (Argument (1));

   Put_Line (Get_State (State));
end Main;
```

118.6 States #3

Goal: implement an on/off indicator for a state machine.

Steps:

1. Implement the function `Is_On`.
2. Implement the procedure `Display_On_Off`.

Requirements:

1. Implement same state machine as in the previous exercise.
2. Function `Is_On` returns:
   - `True` if the machine is on;
   - otherwise, it returns `False`.
3. Procedure `Display_On_Off` displays the message
   - "On" if the machine is on, or
   - "Off" otherwise.
4. `Is_On` must be called in the implementation of `Display_On_Off`.

Remarks:

1. You can implement both subprograms using if expressions.

Listing 2675: is_on.ads

```
function Is_On (State : Integer) return Boolean;
```

Listing 2676: is_on.adb

```
function Is_On (State : Integer) return Boolean is
begin
   return False;
end Is_On;
```

Listing 2677: display_on_off.ads

```
procedure Display_On_Off (State : Integer);
```

Listing 2678: display_on_off.adb

```
with Ada.Text_IO; use Ada.Text_IO;
with Is_On;

procedure Display_On_Off (State : Integer) is
begin
   Put_Line ("");
end Display_On_Off;
```

Listing 2679: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Display_On_Off;
with Is_On;

procedure Main is
   State : Integer;
begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   State := Integer'Value (Argument (1));

   Display_On_Off (State);
   Put_Line (Boolean'Image (Is_On (State)));
end Main;
```

118.7 States #4

Goal: implement a procedure to update the state of a machine.

Steps:

1. Implement the procedure `Set_Next`.

Requirements:

1. Implement the same state machine as in the previous exercise.
2. Procedure `Set_Next` updates the machine's state with the next one in a *circular* manner:
   - In general, after a call to `Set_Next` for an integer variable `N` (`Set_Next (N)`), the new value of `N` must be the next number for that variable `N` (i.e., `N := N'Old + 1`).
     - In other words, a call to `Set_Next (N)` has the same effect as `N := N + 1`.
     - For example, after the statements `N := 1; Set_Next (N);`, we have that `N = 2`.
   - However, if the state is the last valid one for the machine (which, for this exercise, it's 2), the next state must be the first valid one (in this case: 0).
     - In other words, for `N := 2; Set_Next (N);`, we have that `N = 0`.

Remarks:

1. You can use an if expression to implement `Set_Next`.

Listing 2680: set_next.ads

```
procedure Set_Next (State : in out Integer);
```

Listing 2681: set_next.adb

```
procedure Set_Next (State : in out Integer) is
begin
   null;
end Set_Next;
```

Listing 2682: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Set_Next;

procedure Main is
   State : Integer;
begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   State := Integer'Value (Argument (1));

   Set_Next (State);
   Put_Line (Integer'Image (State));
end Main;
```

CHAPTER

NINE

MODULAR PROGRAMMING

119.1 Months

Goal: create a package to display the months of the year.

Steps:

1. Convert the `Months` procedure below to a package.
2. Create the specification and body of the `Months` package.

Requirements:

1. `Months` must contain the declaration of strings for each month of the year, which are stored in three-character constants based on the month's name.
    - For example, the string `"January"` is stored in the constant `Jan`. These strings are then used by the `Display_Months` procedure, which is also part of the `Months` package.

Remarks:

1. The goal of this exercise is to create the `Months` package.
    1. In the code below, `Months` is declared as a procedure.
        - Therefore, we need to *convert* it into a real package.
    2. You have to modify the procedure declaration and implementation in the code below, so that it becomes a package specification and a package body.

Listing 2683: months.ads

```
--  Create specification for Months package, which includes
--  the declaration of the Display_Months procedure.
--
procedure Months;
```

Listing 2684: months.adb

```
--  Create body of Months package, which includes
--  the implementation of the Display_Months procedure.
--
procedure Months is

   procedure Display_Months is
   begin
      Put_Line ("Months:");
      Put_Line ("- " & Jan);
      Put_Line ("- " & Feb);
      Put_Line ("- " & Mar);
      Put_Line ("- " & Apr);
```

(continues on next page)

(continued from previous page)

```
      Put_Line ("- " & May);
      Put_Line ("- " & Jun);
      Put_Line ("- " & Jul);
      Put_Line ("- " & Aug);
      Put_Line ("- " & Sep);
      Put_Line ("- " & Oct);
      Put_Line ("- " & Nov);
      Put_Line ("- " & Dec);
   end Display_Months;

begin
   null;
end Months;
```

Listing 2685: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Months;           use Months;

procedure Main is

   type Test_Case_Index is
     (Months_Chk);

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Months_Chk =>
            Display_Months;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

119.2 Operations

Goal: create a package to perform basic mathematical operations.

Steps:

1. Implement the `Operations` package.
    1. Declare and implement the `Add` function.
    2. Declare and implement the `Subtract` function.
    3. Declare and implement the `Multiply`: function.
    4. Declare and implement the `Divide` function.
2. Implement the `Operations.Test` package

    1. Declare and implement the `Display` procedure.

Requirements:

1. Package `Operations` contains functions for each of the four basic mathematical operations for parameters of **`Integer`** type:
    1. Function `Add` performs the addition of `A` and `B` and returns the result;
    2. Function `Subtract` performs the subtraction of `A` and `B` and returns the result;
    3. Function `Multiply` performs the multiplication of `A` and `B` and returns the result;
    4. Function `Divide` performs the division of `A` and `B` and returns the result.
2. Package `Operations.Test` contains the test environment:
    1. Procedure `Display` must use the functions from the parent (`Operations`) package as indicated by the template in the code below.

Listing 2686: operations.ads

```
package Operations is

   --  Create specification for Operations package, including the
   --  declaration of the functions mentioned above.
   --

end Operations;
```

Listing 2687: operations.adb

```
package body Operations is

   --  Create body of Operations package.
   --

end Operations;
```

Listing 2688: operations-test.ads

```
package Operations.Test is

   --  Create specification for Operations package, including the
   --  declaration of the Display procedure:
   --
   --   procedure Display (A, B : Integer);
   --

end Operations.Test;
```

Listing 2689: operations-test.adb

```
package body Operations.Test is

   --  Implement body of Operations.Test package.
   --

   procedure Display (A, B : Integer) is
      A_Str : constant String := Integer'Image (A);
      B_Str : constant String := Integer'Image (B);
   begin
      Put_Line ("Operations:");
      Put_Line (A_Str & " + " & B_Str & " = "
```

(continues on next page)

(continued from previous page)

```
                & Integer'Image (Add (A, B))
                & ",");
      --  Use the line above as a template and add the rest of the
      --  implementation for Subtract, Multiply and Divide.
   end Display;

end Operations.Test;
```

Listing 2690: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Operations;
with Operations.Test;  use Operations.Test;

procedure Main is

   type Test_Case_Index is
     (Operations_Chk,
      Operations_Display_Chk);

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Operations_Chk =>
            Put_Line ("Add (100, 2) = "
                      & Integer'Image (Operations.Add (100, 2)));
            Put_Line ("Subtract (100, 2) = "
                      & Integer'Image (Operations.Subtract (100, 2)));
            Put_Line ("Multiply (100, 2) = "
                      & Integer'Image (Operations.Multiply (100, 2)));
            Put_Line ("Divide (100, 2) = "
                      & Integer'Image (Operations.Divide (100, 2)));
         when Operations_Display_Chk =>
            Display (10, 5);
            Display ( 1, 2);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

STRONGLY TYPED LANGUAGE

120.1 Colors

Goal: create a package to represent HTML colors in hexadecimal form and its corresponding names.

Steps:

1. Implement the `Color_Types` package.
    1. Declare the `HTML_Color` enumeration.
    2. Declare the `Basic_HTML_Color` enumeration.
    3. Implement the `To_Integer` function.
    4. Implement the `To_HTML_Color` function.

Requirements:

1. Enumeration `HTML_Color` has the following colors:
    - Salmon
    - Firebrick
    - Red
    - Darkred
    - Lime
    - Forestgreen
    - Green
    - Darkgreen
    - Blue
    - Mediumblue
    - Darkblue
2. Enumeration `Basic_HTML_Color` has the following colors: Red, Green, Blue.
3. Function `To_Integer` converts from the `HTML_Color` type to the HTML color code — as integer values in hexadecimal notation.
    - You can find the HTML color codes in the table below.
4. Function `To_HTML_Color` converts from `Basic_HTML_Color` to `HTML_Color`.
5. This is the table to convert from an HTML color to a HTML color code in hexadecimal notation:

Color	HTML color code (hexa)
Salmon	#FA8072
Firebrick	#B22222
Red	#FF0000
Darkred	#8B0000
Lime	#00FF00
Forestgreen	#228B22
Green	#008000
Darkgreen	#006400
Blue	#0000FF
Mediumblue	#0000CD
Darkblue	#00008B

Remarks:

1. In order to express the hexadecimal values above in Ada, use the following syntax: 16#<hex_value># (e.g.: `16#FFFFFF#`).
2. For function `To_Integer`, you may use a **`case`** for this.

Listing 2691: color_types.ads

```
package Color_Types is

   --  Include type declaration for HTML_Color!
   --
   --  type HTML_Color is [...]
   --

   --  Include function declaration for:
   --  function To_Integer (C : HTML_Color) return Integer;

   --  Include type declaration for Basic_HTML_Color!
   --
   --  type Basic_HTML_Color is [...]
   --

   --  Include function declaration for:
   --  - Basic_HTML_Color => HTML_Color
   --
   --  function To_HTML_Color [...];
   --
end Color_Types;
```

Listing 2692: color_types.adb

```
package body Color_Types is

   --  Implement the conversion from HTML_Color to Integer here!
   --
   --  function To_Integer (C : HTML_Color) return Integer is
   --  begin
   --  --  Hint: use 'case' for the HTML colors;
   --  --        use 16#...# for the hexadecimal values.
   --  end To_Integer;

   --  Implement the conversion from Basic_HTML_Color to HTML_Color here!
   --
   --  function To_HTML_Color [...] is

```

120.2 Integers

Goal: implement a package with various integer types.

Steps:

1. Implement the `Int_Types` package.
    1. Declare the integer type `I_100`.
    2. Declare the modular type `U_100`.

3. Implement the `To_I_100` function to convert from the `U_100` type.
4. Implement the `To_U_100` function to convert from the `I_100` type.
5. Declare the derived type `D_50`.
6. Declare the subtype `S_50`.
7. Implement the `To_D_50` function to convert from the `I_100` type.
8. Implement the `To_S_50` function to convert from the `I_100` type.
9. Implement the `To_I_100` function to convert from the `D_50` type.

Requirements:

1. Types `I_100` and `U_100` have values between 0 and 100.
    1. Type `I_100` is an integer type.
    2. Type `U_100` is a modular type.
2. Function `To_I_100` converts from the `U_100` type to the `I_100` type.
3. Function `To_U_100` converts from the `I_100` type to the `U_100` type.
4. Types `D_50` and `S_50` have values between 10 and 50 and use `I_100` as a base type.
    1. `D_50` is a derived type.
    2. `S_50` is a subtype.
5. Function `To_D_50` converts from the `I_100` type to the `D_50` type.
6. Function `To_S_50` converts from the `I_100` type to the `S_50` type.
7. Functions `To_D_50` and `To_S_50` saturate the input values if they are out of range.
    - If the input is less than 10 the output should be 10.
    - If the input is greater than 50 the output should be 50.
8. Function `To_I_100` converts from the `D_50` type to the `I_100` type.

Remarks:

1. For the implementation of functions `To_D_50` and `To_S_50`, you may use the type attributes `D_50'First` and `D_50'Last`:
    1. `D_50'First` indicates the minimum value of the `D_50` type.
    2. `D_50'Last` indicates the maximum value of the `D_50` type.
    3. The same attributes are available for the `S_50` type (`S_50'First` and `S_50'Last`).
2. We could have implemented a function `To_I_100` as well to convert from `S_50` to `I_100`. However, we skip this here because explicit conversions are not needed for subtypes.

Listing 2694: int_types.ads

```
package Int_Types is

   --  Include type declarations for I_100 and U_100!
   --
   --  type I_100 is [...]
   --  type U_100 is [...]
   --

   function To_I_100 (V : U_100) return I_100;

   function To_U_100 (V : I_100) return U_100;

end Main;
```

120.3 Temperatures

Goal: create a package to handle temperatures in Celsius and Kelvin.

Steps:

1. Implement the `Temperature_Types` package.
    1. Declare the `Celsius` type.
    2. Declare the `Int_Celsius` type.

3. Implement the `To_Celsius` function.
4. Implement the `To_Int_Celsius` function.
5. Declare the `Kelvin` type.
6. Implement the `To_Celsius` function to convert from the `Kelvin` type.
7. Implement the `To_Kelvin` function.

Requirements:

1. The custom floating-point types declared in `Temperature_Types` must use a precision of six digits.
2. Types `Celsius` and `Int_Celsius` are used for temperatures in Celsius:
    1. `Celsius` is a floating-point type with a range between -273.15 and 5504.85.
    2. `Int_Celsius` is an integer type with a range between -273 and 5505.
3. Functions `To_Celsius` and `To_Int_Celsius` are used for type conversion:
    1. `To_Celsius` converts from `Int_Celsius` to `Celsius` type.
    2. `To_Int_Celsius` converts from `Celsius` and `Int_Celsius` types:
4. `Kelvin` is a floating-point type for temperatures in Kelvin using a range between 0.0 and 5778.0.
5. The functions `To_Celsius` and `To_Kelvin` are used to convert between temperatures in `Kelvin` and `Celsius`.
    1. In order to convert temperatures in Celsius to Kelvin, you must use the formula $K = C + 273.15$, where:
        - *K* is the temperature in Kelvin, and
        - *C* is the temperature in Celsius.

Remarks:

1. When implementing the `To_Celsius` function for the `Int_Celsius` type:
    1. You'll need to check for the minimum and maximum values of the input values because of the slightly different ranges.
    2. You may use variables of floating-point type (**`Float`**) for intermediate values.
2. For the implementation of the functions `To_Celsius` and `To_Kelvin` (used for converting between `Kelvin` and `Celsius`), you may use a variable of floating-point type (**`Float`**) for intermediate values.

```

CHAPTER

ONE

RECORDS

121.1 Directions

Goal: create a package that handles directions and geometric angles.

Steps:

1. Implement the `Directions` package.
    1. Declare the `Ext_Angle` record.
    2. Implement the `Display` procedure.
    3. Implement the `To_Ext_Angle` function.

Requirements:

1. Record `Ext_Angle` stores information about the extended angle (see remark about *extended angles* below).
2. Procedure `Display` displays information about the extended angle.
    1. You should use the implementation that has been commented out (see code below) as a starting point.
3. Function `To_Ext_Angle` converts a simple angle value to an extended angle (`Ext_Angle` type).

Remarks:

1. We make use of the algorithm implemented in the `Check_Direction` procedure (*chapter on imperative language* (page 9)).
2. For the sake of this exercise, we use the concept of *extended angles*. This includes the actual geometric angle and the corresponding direction (North, South, Northwest, and so on).

Listing 2700: directions.ads

```
package Directions is

   type Angle_Mod is mod 360;

   type Direction is
     (North,
      Northeast,
      East,
      Southeast,
      South,
      Southwest,
      West,
      Northwest);

```

(continues on next page)

(continued from previous page)

```
   function To_Direction (N: Angle_Mod) return Direction;

   --  Include type declaration for Ext_Angle record type:
   --
   --  NOTE: Use the Angle_Mod and Direction types declared above!
   --
   --  type Ext_Angle is [...]
   --

   function To_Ext_Angle (N : Angle_Mod) return Ext_Angle;

   procedure Display (N : Ext_Angle);

end Directions;
```

Listing 2701: directions.adb

```

      when Direction_Chk =>
         Display (To_Ext_Angle (0));
         Display (To_Ext_Angle (30));
         Display (To_Ext_Angle (45));
         Display (To_Ext_Angle (90));
         Display (To_Ext_Angle (91));
         Display (To_Ext_Angle (120));
         Display (To_Ext_Angle (180));
         Display (To_Ext_Angle (250));
         Display (To_Ext_Angle (270));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

121.2 Colors

Goal: create a package to represent HTML colors in RGB format using the hexadecimal form.

Steps:

1. Implement the `Color_Types` package.
    1. Declare the RGB record.
    2. Implement the `To_RGB` function.
    3. Implement the `Image` function for the RGB type.

Requirements:

1. The following table contains the HTML colors and the corresponding value in hexadecimal form for each color element:

Color	Red	Green	Blue
Salmon	#FA	#80	#72
Firebrick	#B2	#22	#22
Red	#FF	#00	#00
Darkred	#8B	#00	#00
Lime	#00	#FF	#00
Forestgreen	#22	#8B	#22
Green	#00	#80	#00
Darkgreen	#00	#64	#00
Blue	#00	#00	#FF
Mediumblue	#00	#00	#CD
Darkblue	#00	#00	#8B

2. The hexadecimal information of each HTML color can be mapped to three color elements: red, green and blue.
    1. Each color element has a value between 0 and 255, or `00` and FF in hexadecimal.
    2. For example, for the color *salmon*, the hexadecimal value of the color elements are:
        - red = FA,
        - green = 80, and
        - blue = 72.
3. Record RGB stores information about HTML colors in RGB format, so that we can retrieve the individual color elements.
4. Function `To_RGB` converts from the `HTML_Color` enumeration to the RGB type based on the information from the table above.
5. Function `Image` returns a string representation of the RGB type in this format:
    - `"(Red => 16#..#, Green => 16#...#, Blue => 16#...# )"`

Remarks:

1. We use the exercise on HTML colors from the previous lab on *Strongly typed language* (page 2331) as a starting point.

Listing 2703: color_types.ads

```
package Color_Types is

   type HTML_Color is
     (Salmon,
      Firebrick,
      Red,
      Darkred,
      Lime,
      Forestgreen,
      Green,
      Darkgreen,
      Blue,
      Mediumblue,
      Darkblue);

      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

121.3 Inventory

Goal: create a simplified inventory system for a store to enter items and keep track of assets.

Steps:

1. Implement the `Inventory_Pkg` package.
    1. Declare the `Item` record.
    2. Implement the `Init` function.
    3. Implement the `Add` procedure.

Requirements:

1. Record `Item` collects information about products from the store.
    1. To keep it simple, this record only contains the name, quantity and price of each item.
    2. The record components are:
        - `Name` of `Item_Name` type;
        - `Quantity` of **`Natural`** type;
        - `Price` of **`Float`** type.
2. Function `Init` returns an initialized item (of `Item` type).
    1. Function `Init` must also display the item name by calling the `To_String` function for the `Item_Name` type.
        - This is already implemented in the code below.
3. Procedure `Add` adds an item to the assets.
    1. Since we want to keep track of the assets, the implementation must accumulate the total value of each item's inventory, the result of multiplying the item quantity and its price.

Listing 2706: inventory_pkg.ads

```
package Inventory_Pkg is

   type Item_Name is
     (Ballpoint_Pen, Oil_Based_Pen_Marker, Feather_Quill_Pen);

   function To_String (I : Item_Name) return String;

   --  Replace type declaration for Item record:
   --
   type Item is null record;

   function Init (Name     : Item_Name;
                  Quantity : Natural;
                  Price    : Float) return Item;

   procedure Add (Assets : in out Float;
                  I      : Item);

end Inventory_Pkg;
```

Listing 2707: inventory_pkg.adb

```
with Ada.Text_IO; use Ada.Text_IO;

package body Inventory_Pkg is

   function To_String (I : Item_Name) return String is
   begin
      case I is
         when Ballpoint_Pen        => return "Ballpoint Pen";
         when Oil_Based_Pen_Marker => return "Oil-based Pen Marker";
         when Feather_Quill_Pen    => return "Feather Quill Pen";
      end case;
   end To_String;

   function Init (Name     : Item_Name;
                  Quantity : Natural;
                  Price    : Float) return Item is
   begin
      Put_Line ("Item: " & To_String (Name) & ".");

      --  Replace return statement with the actual record initialization!
      --
      return (null record);
   end Init;

   procedure Add (Assets : in out Float;
                  I      : Item) is
   begin
      --  Implement the function that adds an item to the inventory here!
      --
      null;
   end Add;

end Inventory_Pkg;
```

Listing 2708: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;

with Inventory_Pkg;     use Inventory_Pkg;

   type Test_Case_Index is
     (Inventory_Chk);

   procedure Display (Assets : Float) is
      package F_IO is new Ada.Text_IO.Float_IO (Float);

      use F_IO;
   begin
      Put ("Assets: $");
      Put (Assets, 1, 2, 0);
      Put (".");
      New_Line;
   end Display;

```

(continues on next page)

(continued from previous page)

```
   procedure Check (TC : Test_Case_Index) is
      I      : Item;
      Assets : Float := 0.0;

      --  Please ignore the following three lines!
      pragma Warnings (Off, "default initialization");
      for Assets'Address use F'Address;
      pragma Warnings (On, "default initialization");
   begin
      case TC is
      when Inventory_Chk =>
         I := Init (Ballpoint_Pen,        185,  0.15);
         Add (Assets, I);
         Display (Assets);

         I := Init (Oil_Based_Pen_Marker, 100,  9.0);
         Add (Assets, I);
         Display (Assets);

         I := Init (Feather_Quill_Pen,      2, 40.0);
         Add (Assets, I);
         Display (Assets);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

TWO

ARRAYS

122.1 Constrained Array

Goal: declare a constrained array and implement operations on it.

Steps:

1. Implement the `Constrained_Arrays` package.
    1. Declare the range type `My_Index`.
    2. Declare the array type `My_Array`.
    3. Declare and implement the `Init` function.
    4. Declare and implement the `Double` procedure.
    5. Declare and implement the `First_Elem` function.
    6. Declare and implement the `Last_Elem` function.
    7. Declare and implement the `Length` function.
    8. Declare the object `A` of `My_Array` type.

Requirements:

1. Range type `My_Index` has a range from 1 to 10.
2. `My_Array` is a constrained array of `Integer` type.
    1. It must make use of the `My_Index` type.
    2. It is therefore limited to 10 elements.
3. Function `Init` returns an array where each element is initialized with the corresponding index.
4. Procedure `Double` doubles the value of each element of an array.
5. Function `First_Elem` returns the first element of the array.
6. Function `Last_Elem` returns the last element of the array.
7. Function `Length` returns the length of the array.
8. Object `A` of `My_Array` type is initialized with:
    1. the values 1 and 2 for the first two elements, and
    2. 42 for all other elements.

Listing 2709: constrained_arrays.ads

```
package Constrained_Arrays is

   --  Complete the type and subprogram declarations:
   --
   --  type My_Index is [...]
   --
   --  type My_Array is [...]
   --
   --  function Init ...
   --
   --  procedure Double ...
   --
   --  function First_Elem ...
   --
   --  function Last_Elem ...
   --
   --  function Length ...
   --
   --  A : ...

end Constrained_Arrays;
```

Listing 2710: constrained_arrays.adb

```
package body Constrained_Arrays is

   --  Create the implementation of the subprograms!
   --

end Constrained_Arrays;
```

Listing 2711: main.adb

```
with Ada.Command_Line;   use Ada.Command_Line;
with Ada.Text_IO;        use Ada.Text_IO;

with Constrained_Arrays; use Constrained_Arrays;

procedure Main is
   type Test_Case_Index is
     (Range_Chk,
      Array_Range_Chk,
      A_Obj_Chk,
      Init_Chk,
      Double_Chk,
      First_Elem_Chk,
      Last_Elem_Chk,
      Length_Chk);

   procedure Check (TC : Test_Case_Index) is
      AA : My_Array;

      procedure Display (A : My_Array) is
      begin
         for I in A'Range loop
            Put_Line (Integer'Image (A (I)));
         end loop;
      end Display;

      procedure Local_Init (A : in out My_Array) is
```

(continues on next page)

(continued from previous page)

```
      begin
         A := (100, 90, 80, 10, 20, 30, 40, 60, 50, 70);
      end Local_Init;
   begin
      case TC is
      when Range_Chk =>
         for I in My_Index loop
            Put_Line (My_Index'Image (I));
         end loop;
      when Array_Range_Chk =>
         for I in My_Array'Range loop
            Put_Line (My_Index'Image (I));
         end loop;
      when A_Obj_Chk =>
         Display (A);
      when Init_Chk =>
         AA := Init;
         Display (AA);
      when Double_Chk =>
         Local_Init (AA);
         Double (AA);
         Display (AA);
      when First_Elem_Chk =>
         Local_Init (AA);
         Put_Line (Integer'Image (First_Elem (AA)));
      when Last_Elem_Chk =>
         Local_Init (AA);
         Put_Line (Integer'Image (Last_Elem (AA)));
      when Length_Chk =>
         Put_Line (Integer'Image (Length (AA)));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

122.2 Colors: Lookup-Table

Goal: rewrite a package to represent HTML colors in RGB format using a lookup table.

Steps:

1. Implement the `Color_Types` package.
    1. Declare the array type `HTML_Color_RGB`.
    2. Declare the `To_RGB_Lookup_Table` object and initialize it.
    3. Adapt the implementation of the `To_RGB` function.

Requirements:

1. Array type `HTML_Color_RGB` is used for the table.
2. The `To_RGB_Lookup_Table` object of `HTML_Color_RGB` type contains the lookup table.

- This table must be implemented as an array of constant values.

3. The implementation of the To_RGB function must use the To_RGB_Lookup_Table object.

Remarks:

1. This exercise is based on the HTML colors exercise from a previous lab (*Records* (page 2341)).
2. In the previous implementation, you could use a **case** statement to implement the To_RGB function. Here, you must rewrite the function using a look-up table.
    1. The implementation of the To_RGB function below includes the case statement as commented-out code. You can use this as your starting point: you just need to copy it and convert the case statement to an array declaration.
    1. Don't use a case statement to implement the To_RGB function. Instead, write code that accesses To_RGB_Lookup_Table to get the correct value.
3. The following table contains the HTML colors and the corresponding value in hexadecimal form for each color element:

Color	Red	Green	Blue
Salmon	#FA	#80	#72
Firebrick	#B2	#22	#22
Red	#FF	#00	#00
Darkred	#8B	#00	#00
Lime	#00	#FF	#00
Forestgreen	#22	#8B	#22
Green	#00	#80	#00
Darkgreen	#00	#64	#00
Blue	#00	#00	#FF
Mediumblue	#00	#00	#CD
Darkblue	#00	#00	#8B

Listing 2712: color_types.ads

```
1  package Color_Types is
2
3     type HTML_Color is
4       (Salmon,
5        Firebrick,
6        Red,
7        Darkred,
8        Lime,
9        Forestgreen,
10       Green,
11       Darkgreen,
12       Blue,
13       Mediumblue,
14       Darkblue);
15
16    subtype Int_Color is Integer range 0 .. 255;
17
18    type RGB is record
19       Red   : Int_Color;
20       Green : Int_Color;
21       Blue  : Int_Color;
22    end record;
23
```

(continues on next page)

(continued from previous page)

```
   function To_RGB (C : HTML_Color) return RGB;

   function Image (C : RGB) return String;

   --  Declare array type for lookup table here:
   --
   --  type HTML_Color_RGB is ...

   --  Declare lookup table here:
   --
   --  To_RGB_Lookup_Table : ...

end Color_Types;
```

Listing 2713: color_types.adb

```
with Ada.Integer_Text_IO;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

122.3 Unconstrained Array

Goal: declare an unconstrained array and implement operations on it.

Steps:

1. Implement the `Unconstrained_Arrays` package.
    1. Declare the `My_Array` type.
    2. Declare and implement the `Init` procedure.
    3. Declare and implement the `Init` function.
    4. Declare and implement the `Double` procedure.
    5. Declare and implement the `Diff_Prev_Elem` function.

Requirements:

1. My_Array is an unconstrained array (with a **Positive** range) of **Integer** elements.
2. Procedure Init initializes each element with the index starting with the last one.
   - For example, for an array of 3 elements where the index of the first element is 1 (My_Array (1 .. 3)), the values of these elements after a call to Init must be (3, 2, 1).
3. Function Init returns an array based on the length L and start index I provided to the Init function.
   1. I indicates the index of the first element of the array.
   2. L indicates the length of the array.
   3. Both I and L must be positive.
   4. This is its declaration: `function Init (I, L : Positive) return My_Array;`.
   5. You must initialize the elements of the array in the same manner as for the Init procedure described above.
4. Procedure Double doubles each element of an array.
5. Function Diff_Prev_Elem returns — for each element of an input array A — an array with the difference between an element of array A and the previous element.
   1. For the first element, the difference must be zero.
   2. For example:
      - **INPUT**: (2, 5, 15)
      - **RETURN** of Diff_Prev_Elem: (0, 3, 10), where
        - 0 is the constant difference for the first element;
        - 5 - 2 = 3 is the difference between the second and the first elements of the input array;
        - 15 - 5 = 10 is the difference between the third and the second elements of the input array.

Remarks:

1. For an array A, you can retrieve the index of the last element with the attribute 'Last.
   1. For example: `Y : Positive := A'Last;`
   2. This can be useful during the implementation of procedure Init.
2. For the implementation of the Init function, you can call the Init procedure to initialize the elements. By doing this, you avoid code duplication.
3. Some hints about attributes:
   1. You can use the range attribute (A'Range) to retrieve the range of an array A.
   2. You can also use the range attribute in the declaration of another array (e.g.: B : My_Array (A'Range)).
   3. Alternatively, you can use the A'First and A'Last attributes in an array declaration.

39          Init (AB);
40          Display (AA);
41          Display (AB);
42       when Double_Chk =>
43          Local_Init (AB);
44          Double (AB);
45          Display (AB);
46       when Diff_Prev_Chk =>
47          Local_Init (AB);
48          AB := Diff_Prev_Elem (AB);
49          Display (AB);
50       when Diff_Prev_Single_Chk =>
51          declare
52             A1 : My_Array (1 .. 1) := (1 => 42);
53          begin
54             A1 := Diff_Prev_Elem (A1);
55             Display (A1);
56          end;
57       end case;
58    end Check;
59
60 begin
61    if Argument_Count < 1 then
62       Put_Line ("ERROR: missing arguments! Exiting...");
63       return;
64    elsif Argument_Count > 1 then
65       Put_Line ("Ignoring additional arguments...");
66    end if;
67
68    Check (Test_Case_Index'Value (Argument (1)));
69 end Main;
```

122.4 Product info

Goal: create a system to keep track of quantities and prices of products.

Steps:

1. Implement the `Product_Info_Pkg` package.
    1. Declare the array type `Product_Infos`.
    2. Declare the array type `Currency_Array`.
    3. Implement the `Total` procedure.
    4. Implement the `Total` function returning an array of `Currency_Array` type.
    5. Implement the `Total` function returning a single value of `Currency` type.

Requirements:

1. Quantity of an individual product is represented by the `Quantity` subtype.

2. Price of an individual product is represented by the `Currency` subtype.
3. Record type `Product_Info` deals with information for various products.
4. Array type `Product_Infos` is used to represent a list of products.
5. Array type `Currency_Array` is used to represent a list of total values of individual products (see more details below).
6. Procedure `Total` receives an input array of products.
    1. It outputs an array with the total value of each product using the `Currency_Array` type.
    2. The total value of an individual product is calculated by multiplying the quantity for this product by its price.
7. Function `Total` returns an array of `Currency_Array` type.
    1. This function has the same purpose as the procedure `Total`.
    2. The difference is that the function returns an array instead of providing this array as an output parameter.
8. The second function `Total` returns a single value of `Currency` type.
    1. This function receives an array of products.
    2. It returns a single value corresponding to the total value for all products in the system.

Remarks:

1. You can use `Currency (Q)` to convert from an element `Q` of `Quantity` type to the `Currency` type.
    1. As you might remember, Ada requires an explicit conversion in calculations where variables of both integer and floating-point types are used.
    2. In our case, the `Quantity` subtype is based on the **`Integer`** type and the `Currency` subtype is based on the **`Float`** type, so a conversion is necessary in calculations using those types.

Listing 2718: product_info_pkg.ads

```
package Product_Info_Pkg is

   subtype Quantity is Natural;

   subtype Currency is Float;

   type Product_Info is record
      Units : Quantity;
      Price : Currency;
   end record;

   --  Complete the type declarations:
   --
   --  type Product_Infos is ...
   --
   --  type Currency_Array is ...

   procedure Total (P   : Product_Infos;
                    Tot : out Currency_Array);

   function Total (P : Product_Infos) return Currency_Array;

   function Total (P : Product_Infos) return Currency;
```

25             New_Line;
26          end loop;
27       end Display;
28
29       procedure Local_Init (P : in out Product_Infos) is
30       begin
31          P := ((1,   0.5),
32                (2,  10.0),
33                (5,  40.0),
34                (10, 10.0),
35                (10, 20.0));
36       end Local_Init;
37
38    begin
39       Currency_IO.Default_Fore := 1;
```

(continues on next page)

(continued from previous page)

```
      Currency_IO.Default_Aft  := 2;
      Currency_IO.Default_Exp  := 0;

      case TC is
      when Total_Func_Chk =>
         Local_Init (P);
         Tots := Total (P);
         Display (Tots);
      when Total_Proc_Chk =>
         Local_Init (P);
         Total (P, Tots);
         Display (Tots);
      when Total_Value_Chk =>
         Local_Init (P);
         Tot := Total (P);
         Currency_IO.Put (Tot);
         New_Line;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

122.5 String_10

Goal: work with constrained string types.

Steps:

1. Implement the `Strings_10` package.
    1. Declare the `String_10` type.
    2. Implement the `To_String_10` function.

Requirements:

1. The constrained string type `String_10` is an array of ten characters.
2. Function `To_String_10` returns constrained strings of `String_10` type based on an input parameter of **`String`** type.
    - For strings that are more than 10 characters, omit everything after the 11th character.
    - For strings that are fewer than 10 characters, pad the string with `' '` characters until it is 10 characters.

Remarks:

1. Declaring `String_10` as a subtype of **`String`** is the easiest way.
    - You may declare it as a new type as well. However, this requires some adaptations in the `Main` test procedure.
2. You can use **`Integer`**`'Min` to calculate the minimum of two integer values.

Listing 2721: strings_10.ads

```
package Strings_10 is

   --  Complete the type and subprogram declarations:
   --

   --  subtype String_10 is ...;

   --  Using "type String_10 is..." is possible, too. However, it
   --  requires a custom Put_Line procedure that is called in Main:
   --  procedure Put_Line (S : String_10);

   --  function To_String_10 ...;

end Strings_10;
```

Listing 2722: strings_10.adb

```
package body Strings_10 is

   --  Complete the subprogram declaration and implementation:
   --
   --  function To_String_10 ... is

end Strings_10;
```

Listing 2723: main.adb

```
with Ada.Command_Line;   use Ada.Command_Line;
with Ada.Text_IO;        use Ada.Text_IO;

with Strings_10;         use Strings_10;

procedure Main is
   type Test_Case_Index is
     (String_10_Long_Chk,
      String_10_Short_Chk);

   procedure Check (TC : Test_Case_Index) is
      SL   : constant String := "And this is a long string just for testing...";
      SS   : constant String := "Hey!";
      S_10 : String_10;

   begin
      case TC is
      when String_10_Long_Chk =>
         S_10 := To_String_10 (SL);
         Put_Line (String (S_10));
      when String_10_Short_Chk =>
         S_10 := (others => ' ');
         S_10 := To_String_10 (SS);
         Put_Line (String (S_10));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Ada.Text_IO.Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
```

(continues on next page)

(continued from previous page)

```
      Ada.Text_IO.Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

122.6 List of Names

Goal: create a system for a list of names and ages.

Steps:

1. Implement the `Names_Ages` package.
    1. Declare the `People_Array` array type.
    2. Complete the declaration of the `People` record type with the `People_A` element of `People_Array` type.
    3. Implement the `Add` procedure.
    4. Implement the `Reset` procedure.
    5. Implement the `Get` function.
    6. Implement the `Update` procedure.
    7. Implement the `Display` procedure.

Requirements:

1. Each person is represented by the `Person` type, which is a record containing the name and the age of that person.
2. `People_Array` is an unconstrained array of `Person` type with a positive range.
3. The `Max_People` constant is set to 10.
4. Record type `People` contains:
    1. The `People_A` element of `People_Array` type.
    2. This array must be constrained by the `Max_People` constant.
5. Procedure `Add` adds a person to the list.
    1. By default, the age of this person is set to zero in this procedure.
6. Procedure `Reset` resets the list.
7. Function `Get` retrieves the age of a person from the list.
8. Procedure `Update` updates the age of a person in the list.
9. Procedure `Display` shows the complete list using the following format:
    1. The first line must be `LIST OF NAMES:`. It is followed by the name and age of each person in the next lines.
    2. For each person on the list, the procedure must display the information in the following format:

```
NAME: XXXX
AGE: YY
```

Remarks:

1. In the implementation of procedure Add, you may use an index to indicate the last valid position in the array — see `Last_Valid` in the code below.
2. In the implementation of procedure `Display`, you should use the `Trim` function from the `Ada.Strings.Fixed` package to format the person's name — for example: `Trim (P.Name, Right)`.
3. You may need the `Integer'Min (A, B)` and the `Integer'Max (A, B)` functions to get the minimum and maximum values in a comparison between two integer values A and B.
4. Fixed-length strings can be initialized with whitespaces using the **others** syntax. For example: `S : String_10 := (others => ' ');`
5. You may implement additional subprograms to deal with other types declared in the `Names_Ages` package below, such as the `Name_Type` and the `Person` type.
    1. For example, a function `To_Name_Type` to convert from **String** to `Name_Type` might be useful.
    2. Take a moment to reflect on which additional subprograms could be useful as well.

Listing 2724: names_ages.ads

```
package Names_Ages is

   Max_People : constant Positive := 10;

   subtype Name_Type is String (1 .. 50);

   type Age_Type is new Natural;

   type Person is record
      Name  : Name_Type;
      Age   : Age_Type;
   end record;

   --  Add type declaration for People_Array record:
   --
   --  type People_Array is ...;

   --  Replace type declaration for People record. You may use the
   --  following template:
   --
   --  type People is record
   --     People_A   : People_Array ...;
   --     Last_Valid : Natural;
   --  end record;
   --
   type People is null record;

   procedure Reset (P : in out People);

   procedure Add (P    : in out People;
                  Name : String);

   function Get (P    : People;
                 Name : String) return Age_Type;

   procedure Update (P    : in out People;
                     Name : String;
                     Age  : Age_Type);

   procedure Display (P : People);
```

         Add (P, "John");
         Add (P, "Patricia");
         Add (P, "Josh");
         Display (P);
         Update (P, "John",     18);
         Update (P, "Patricia", 35);
         Update (P, "Josh",     53);
         Display (P);
      when Get_Age_Chk =>
         Reset (P);
         Add (P, "Peter");
         Update (P, "Peter", 45);
         Put_Line ("Peter is "
                   & Age_Type'Image (Get (P, "Peter"))
                   & " years old.");
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Ada.Text_IO.Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Ada.Text_IO.Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

THREE

MORE ABOUT TYPES

123.1 Aggregate Initialization

Goal: initialize records and arrays using aggregates.

Steps:

1. Implement the `Aggregates` package.
    1. Create the record type Rec.
    2. Create the array type `Int_Arr`.
    3. Implement the `Init` procedure that outputs a record of Rec type.
    4. Implement the `Init_Some` procedure.
    5. Implement the `Init` procedure that outputs an array of `Int_Arr` type.

Requirements:

1. Record type Rec has four components of **`Integer`** type. These are the components with the corresponding default values:
    - `W` = 10
    - `X` = 11
    - `Y` = 12
    - `Z` = 13
2. Array type `Int_Arr` has 20 elements of **`Integer`** type (with indices ranging from 1 to 20).
3. The first `Init` procedure outputs a record of Rec type where:
    1. `X` is initialized with 100,
    2. `Y` is initialized with 200, and
    3. the remaining elements use their default values.
4. Procedure `Init_Some` outputs an array of `Int_Arr` type where:
    1. the first five elements are initialized with the value 99, and
    2. the remaining elements are initialized with the value 100.
5. The second `Init` procedure outputs an array of `Int_Arr` type where:
    1. all elements are initialized with the value 5.

Listing 2727: aggregates.ads

```
package Aggregates is

   --  type Rec is ...;

   --  type Int_Arr is ...;

   procedure Init;

   --  procedure Init_Some ...;

   --  procedure Init ...;

end Aggregates;
```

Listing 2728: aggregates.adb

```
package body Aggregates is

   procedure Init is null;

end Aggregates;
```

Listing 2729: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;

with Aggregates;        use Aggregates;

procedure Main is
   --  Remark: the following line is not relevant.
   F   : array (1 .. 10) of Float := (others => 42.42)
     with Unreferenced;

   type Test_Case_Index is
     (Default_Rec_Chk,
      Init_Rec_Chk,
      Init_Some_Arr_Chk,
      Init_Arr_Chk);

   procedure Check (TC : Test_Case_Index) is
      A : Int_Arr;
      R : Rec;
      DR : constant Rec := (others => <>);
   begin
      case TC is
         when Default_Rec_Chk =>
            R := DR;
            Put_Line ("Record Default:");
            Put_Line ("W => " & Integer'Image (R.W));
            Put_Line ("X => " & Integer'Image (R.X));
            Put_Line ("Y => " & Integer'Image (R.Y));
            Put_Line ("Z => " & Integer'Image (R.Z));
         when Init_Rec_Chk =>
            Init (R);
            Put_Line ("Record Init:");
            Put_Line ("W => " & Integer'Image (R.W));
            Put_Line ("X => " & Integer'Image (R.X));
            Put_Line ("Y => " & Integer'Image (R.Y));
            Put_Line ("Z => " & Integer'Image (R.Z));
```

(continues on next page)

(continued from previous page)

```
         when Init_Some_Arr_Chk =>
            Init_Some (A);
            Put_Line ("Array Init_Some:");
            for I in A'Range loop
               Put_Line (Integer'Image (I) & " "
                         & Integer'Image (A (I)));
            end loop;
         when Init_Arr_Chk =>
            Init (A);
            Put_Line ("Array Init:");
            for I in A'Range loop
               Put_Line (Integer'Image (I) & " "
                         & Integer'Image (A (I)));
            end loop;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

123.2 Versioning

Goal: implement a simple package for source-code versioning.

Steps:

1. Implement the `Versioning` package.
    1. Declare the record type `Version`.
    2. Implement the `Convert` function that returns a string.
    3. Implement the `Convert` function that returns a floating-point number.

Requirements:

1. Record type `Version` has the following components of **`Natural`** type:
    1. `Major`,
    2. `Minor`, and
    3. `Maintenance`.
2. The first `Convert` function returns a string containing the version number.
3. The second `Convert` function returns a floating-point value.
    1. For this floating-point value:
        1. the number before the decimal point must correspond to the major number, and
        2. the number after the decimal point must correspond to the minor number.
        3. the maintenance number is ignored.
    2. For example, version "1.3.5" is converted to the floating-point value `1.3`.

3. An obvious limitation of this function is that it can only handle one-digit numbers for the minor component.
   - For example, we cannot convert version "1.10.0" to a reasonable value with the approach described above. The result of the call `Convert ((1, 10, 0))` is therefore unspecified.
   - For the scope of this exercise, only version numbers with one-digit components are checked.

Remarks:

1. We use overloading for the `Convert` functions.
2. For the function `Convert` that returns a string, you can make use of the `Image_Trim` function, as indicated in the source-code below — see package body of `Versioning`.

Listing 2730: versioning.ads

```
package Versioning is

   --  type Version is record...

   --  function Convert ...

   --  function Convert

end Versioning;
```

Listing 2731: versioning.adb

```
with Ada.Strings; use Ada.Strings;
with Ada.Strings.Fixed; use Ada.Strings.Fixed;

package body Versioning is

   function Image_Trim (N : Natural) return String is
      S_N : constant String := Trim (Natural'Image (N), Left);
   begin
      return S_N;
   end Image_Trim;

   --  function Convert ...
   --     S_Major : constant String := Image_Trim (V.Major);
   --     S_Minor : constant String := Image_Trim (V.Minor);
   --     S_Maint : constant String := Image_Trim (V.Maintenance);
   --  begin
   --  end Convert;

   --  function Convert ...
   --  begin
   --  end Convert;

end Versioning;
```

Listing 2732: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;

with Versioning;        use Versioning;

procedure Main is
```

(continues on next page)

(continued from previous page)

```
   type Test_Case_Index is
     (Ver_String_Chk,
      Ver_Float_Chk);

   procedure Check (TC : Test_Case_Index) is
      V : constant Version := (1, 3, 23);
   begin
      case TC is
         when Ver_String_Chk =>
            Put_Line (Convert (V));
         when Ver_Float_Chk =>
            Put_Line (Float'Image (Convert (V)));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

123.3 Simple todo list

Goal: implement a simple to-do list system.

Steps:

1. Implement the `Todo_Lists` package.
    1. Declare the `Todo_Item` type.
    2. Declare the `Todo_List` type.
    3. Implement the `Add` procedure.
    4. Implement the `Display` procedure.

Requirements:

1. `Todo_Item` type is used to store a to-do item.
    1. It should be implemented as an access type to strings.
2. `Todo_Items` type is an array of to-do items.
    1. It should be implemented as an unconstrained array with positive range.
3. `Todo_List` type is the container for all to-do items.
    1. This record type must have a discriminant for the maximum number of elements of the list.
    2. In order to store the to-do items, it must contain a component named `Items` of `Todo_Items` type.
    3. Don't forget to keep track of the last element added to the list!
        - You should declare a `Last` component in the record.
4. Procedure `Add` adds items (of `Todo_Item` type) to the list (of `Todo_List` type).

    1. This requires allocating a string for the access type.
    2. An item can only be added to the list if the list isn't full yet — see next point for details on error handling.
5. Since the number of items that can be stored on the list is limited, the list might eventually become full in a call to Add.
    1. You must write code in the implementation of the Add procedure that verifies this condition.
    2. If the procedure detects that the list is full, it must display the following message: "ERROR: list is full!".
6. Procedure Display is used to display all to-do items.
    1. The header (first line) must be TO-DO LIST.
    2. It must display one item per line.

Remarks:

1. We use access types and unconstrained arrays in the implementation of the Todo_Lists package.

Listing 2733: todo_lists.ads

```
package Todo_Lists is

   --  Replace by actual type declaration
   type Todo_Item is null record;

   --  Replace by actual type declaration
   type Todo_Items is null record;

   --  Replace by actual type declaration
   type Todo_List is null record;

   procedure Add (Todos : in out Todo_List;
                  Item  : String);

   procedure Display (Todos : Todo_List);

end Todo_Lists;
```

Listing 2734: todo_lists.adb

```
with Ada.Text_IO; use Ada.Text_IO;

package body Todo_Lists is

   procedure Add (Todos : in out Todo_List;
                  Item  : String) is
   begin
      Put_Line ("ERROR: list is full!");
   end Add;

   procedure Display (Todos : Todo_List) is
   begin
      null;
   end Display;

end Todo_Lists;
```

Listing 2735: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;

with Todo_Lists;        use Todo_Lists;

procedure Main is
   type Test_Case_Index is
     (Todo_List_Chk);

   procedure Check (TC : Test_Case_Index) is
      T : Todo_List (10);
   begin
      case TC is
         when Todo_List_Chk =>
            Add (T, "Buy milk");
            Add (T, "Buy tea");
            Add (T, "Buy present");
            Add (T, "Buy tickets");
            Add (T, "Pay electricity bill");
            Add (T, "Schedule dentist appointment");
            Add (T, "Call sister");
            Add (T, "Revise spreasheet");
            Add (T, "Edit entry page");
            Add (T, "Select new design");
            Add (T, "Create upgrade plan");
            Display (T);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

123.4 Price list

Goal: implement a list containing prices

Steps:

1. Implement the `Price_Lists` package.
    1. Declare the `Price_Type` type.
    2. Declare the `Price_List` record.
    3. Implement the `Reset` procedure.
    4. Implement the `Add` procedure.
    5. Implement the `Get` function.
    6. Implement the `Display` procedure.

Requirements:

1. `Price_Type` is a decimal fixed-point data type with a delta of two digits (e.g. `0.01`) and twelve digits in total.
2. `Price_List` is a record type that contains the price list.
    1. This record type must have a discriminant for the maximum number of elements of the list.
3. Procedure `Reset` resets the list.
4. Procedure `Add` adds a price to the list.
    1. You should keep track of the last element added to the list.
5. Function `Get` retrieves a price from the list using an index.
    1. This function returns a record instance of `Price_Result` type.
    2. `Price_Result` is a variant record containing:
        1. the Boolean component `Ok`, and
        2. the component `Price` (of `Price_Type`).
    3. The returned value of `Price_Result` type is one of the following:
        1. If the index specified in a call to `Get` contains a valid (initialized) price, then
            - `Ok` is set to **`True`**, and
            - the `Price` component contains the price for that index.
        2. Otherwise:
            - `Ok` is set to **`False`**, and
            - the `Price` component is not available.
6. Procedure `Display` shows all prices from the list.
    1. The header (first line) must be `PRICE LIST`.
    2. The remaining lines contain one price per line.
    3. For example:
        - For the following code:

```
procedure Test is
   L : Price_List (10);
begin
   Reset (L);
   Add (L, 1.45);
   Add (L, 2.37);
   Display (L);
end Test;
```

        - The output is:

```
PRICE LIST
 1.45
 2.37
```

Remarks:

1. To implement the package, you'll use the following features of the Ada language:
    1. decimal fixed-point types;
    2. records with discriminants;
    3. dynamically-sized record types;

4. variant records.

2. For record type `Price_List`, you may use an unconstrained array as a component of the record and use the discriminant in the component declaration.

Listing 2736: price_lists.ads

```
package Price_Lists is

   --  Replace by actual type declaration
   type Price_Type is new Float;

   --  Replace by actual type declaration
   type Price_List is null record;

   --  Replace by actual type declaration
   type Price_Result is null record;

   procedure Reset (Prices : in out Price_List);

   procedure Add (Prices : in out Price_List;
                  Item   : Price_Type);

   function Get (Prices : Price_List;
                 Idx    : Positive) return Price_Result;

   procedure Display (Prices : Price_List);

end Price_Lists;
```

Listing 2737: price_lists.adb

```
package body Price_Lists is

   procedure Reset (Prices : in out Price_List) is
   begin
      null;
   end Reset;

   procedure Add (Prices : in out Price_List;
                  Item   : Price_Type) is
   begin
      null;
   end Add;

   function Get (Prices : Price_List;
                 Idx    : Positive) return Price_Result is
   begin
      null;
   end Get;

   procedure Display (Prices : Price_List) is
   begin
      null;
   end Display;

end Price_Lists;
```

      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

FOUR

PRIVACY

124.1 Directions

Goal: create a package that handles directions and geometric angles using a previous implementation.

Steps:

1. Fix the implementation of the `Test_Directions` procedure.

Requirements:

1. The implementation of the `Test_Directions` procedure must compile correctly.

Remarks:

1. This exercise is based on the *Directions* exercise from the *Records* (page 2341) labs.
    1. In this version, however, `Ext_Angle` is a private type.
2. In the implementation of the `Test_Directions` procedure below, the Ada developer tried to initialize `All_Directions` — an array of `Ext_Angle` type — with aggregates.
    1. Since we now have a private type, the compiler complains about this initialization.
3. To fix the implementation of the `Test_Directions` procedure, you should use the appropriate function from the `Directions` package.
4. The initialization of `All_Directions` in the code below contains a consistency error where the angle doesn't match the assessed direction.
    1. See if you can spot this error!
    2. This kind of errors can happen when record components that have correlated information are initialized individually without consistency checks — using private types helps to avoid the problem by requiring initialization routines that can enforce consistency.

Listing 2739: directions.ads

```
package Directions is

   type Angle_Mod is mod 360;

   type Direction is
     (North,
      Northwest,
      West,
      Southwest,
      South,
      Southeast,
      East);

```

(continues on next page)

(continued from previous page)

```
   function To_Direction (N : Angle_Mod) return Direction;

   type Ext_Angle is private;

   function To_Ext_Angle (N : Angle_Mod) return Ext_Angle;

   procedure Display (N : Ext_Angle);

private

   type Ext_Angle is record
      Angle_Elem     : Angle_Mod;
      Direction_Elem : Direction;
   end record;

end Directions;
```

Listing 2740: directions.adb

```
with Ada.Text_IO; use Ada.Text_IO;

package body Directions is

   procedure Display (N : Ext_Angle) is
   begin
      Put_Line ("Angle: "
                & Angle_Mod'Image (N.Angle_Elem)
                & " => "
                & Direction'Image (N.Direction_Elem)
                & ".");
   end Display;

   function To_Direction (N : Angle_Mod) return Direction is
   begin
      case N is
         when   0        => return East;
         when   1 ..  89 => return Northwest;
         when  90        => return North;
         when  91 .. 179 => return Northwest;
         when 180        => return West;
         when 181 .. 269 => return Southwest;
         when 270        => return South;
         when 271 .. 359 => return Southeast;
      end case;
   end To_Direction;

   function To_Ext_Angle (N : Angle_Mod) return Ext_Angle is
   begin
      return (Angle_Elem     => N,
              Direction_Elem => To_Direction (N));
   end To_Ext_Angle;

end Directions;
```

Listing 2741: test_directions.adb

```
with Directions; use Directions;

procedure Test_Directions is
   type Ext_Angle_Array is array (Positive range <>) of Ext_Angle;
```

(continues on next page)

(continued from previous page)

```
   All_Directions : constant Ext_Angle_Array (1 .. 6)
     := ((0,   East),
         (45,  Northwest),
         (90,  North),
         (91,  North),
         (180, West),
         (270, South));

begin
   for I in All_Directions'Range loop
      Display (All_Directions (I));
   end loop;

end Test_Directions;
```

with Ada.Text_IO;       use Ada.Text_IO;

with Test_Directions;

procedure Main is
     type Test_Case_Index is
     (Direction_Chk);

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
      when Direction_Chk =>
         Test_Directions;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

124.2 Limited Strings

Goal: work with `limited private` types.

Steps:

1. Implement the `Limited_Strings` package.
    1. Implement the `Copy` function.
    2. Implement the `=` operator.

Requirements:

1. For both `Copy` and `=`, the two parameters may refer to strings with different lengths.

We'll limit the implementation to just take the minimum length:

1. In case of copying the string "Hello World" to a string with 5 characters, the copied string is "Hello":

```
   S1 : constant Lim_String := Init ("Hello World");
   S2 :          Lim_String := Init (5);
begin
   Copy (From => S1, To => S2);
   Put_Line (S2);     --  This displays "Hello".
```

2. When comparing "Hello World" to "Hello", the = operator indicates that these strings are equivalent:

```
   S1 : constant Lim_String := Init ("Hello World");
   S2 : constant Lim_String := Init ("Hello");
begin
   if S1 = S2 then
      --  True => This branch gets selected.
```

2. When copying from a short string to a longer string, the remaining characters of the longer string must be initialized with underscores (_). For example:

```
   S1 : constant Lim_String := Init ("Hello");
   S2 :          Lim_String := Init (10);
begin
   Copy (From => S1, To => S2);
   Put_Line (S2);     --  This displays "Hello_____".
```

Remarks:

1. As we've discussed in the course:
    1. Variables of limited types have the following limitations:
        - they cannot be assigned to;
        - they don't have an equality operator (=).
    2. We can, however, define our own, custom subprograms to circumvent these limitations:
        - In order to copy instances of a limited type, we can define a custom Copy procedure.
        - In order to compare instances of a limited type, we can define an = operator.
2. You can use the `Min_Last` constant — which is already declared in the implementation of these subprograms — in the code you write.
3. Some details about the `Limited_Strings` package:
    1. The `Lim_String` type acts as a container for strings.
        1. In the private part, `Lim_String` is declared as an access type to a **`String`**.
    2. There are two versions of the `Init` function that initializes an object of `Lim_String` type:
        1. The first one takes another string.
        2. The second one receives the number of characters for a string *container*.
    3. Procedure `Put_Line` displays object of `Lim_String` type.
    4. The design and implementation of the `Limited_Strings` package is very simplistic.
        1. A good design would have better handling of access types, for example.

Listing 2743: limited_strings.ads

```
package Limited_Strings is

   type Lim_String is limited private;

   function Init (S : String) return Lim_String;

   function Init (Max : Positive) return Lim_String;

   procedure Put_Line (LS : Lim_String);

   procedure Copy (From :        Lim_String;
                   To   : in out Lim_String);

   function "=" (Ref, Dut : Lim_String) return Boolean;

```

124.3 Bonus exercise

In previous labs, we had many source-code snippets containing records that could be declared private. The source-code for the exercise above (*Directions*) is an example: we've modified the type declaration of `Ext_Angle`, so that the record is now private. Encapsulating the record components — by declaring record components in the private part — makes the code safer. Also, because many of the code snippets weren't making use of record components directly (but handling record types via the API instead), they continue to work fine after these modifications.

This exercise doesn't contain any source-code. In fact, the **goal** here is to modify previous labs, so that the record declarations are made private. You can look into those labs, modify the type declarations, and recompile the code. The corresponding test-cases must still pass.

If no other changes are needed apart from changes in the declaration, then that indicates we have used good programming techniques in the original code. On the other hand, if further changes are needed, then you should investigate why this is the case.

Also note that, in some cases, you can move support types into the private part of the specification without affecting its compilation. This is the case, for example, for the `People_Array` type of the *List of Names* lab mentioned below. You should, in fact, keep only relevant types and subprograms in the public part and move all support declarations to the private part of the specification whenever possible.

Below, you find the selected labs that you can work on, including changes that you should make. In case you don't have a working version of the source-code of previous labs, you can look into the corresponding solutions.

124.3.1 Colors

Chapter: *Records* (page 2341)

Steps:

1. Change declaration of RGB type to **`private`**.

Requirements:

1. Implementation must compile correctly and test cases must pass.

124.3.2 List of Names

Chapter: *Arrays* (page 2351)

Steps:

1. Change declaration of `Person` and `People` types to **`limited private`**.
2. Move type declaration of `People_Array` to private part.

Requirements:

1. Implementation must compile correctly and test cases must pass.

124.3.3 Price List

Chapter: *More About Types* (page 2369)

Steps:

1. Change declaration of `Price_List` type to **`limited private`**.

Requirements:

1. Implementation must compile correctly and test cases must pass.

CHAPTER

FIVE

GENERICS

125.1 Display Array

Goal: create a generic procedure that displays the elements of an array.

Steps:

1. Implement the generic procedure `Display_Array`.

Requirements:

1. Generic procedure `Display_Array` displays the elements of an array.
    1. It uses the following scheme:
        - First, it displays a header.
        - Then, it displays the elements of the array.
    2. When displaying the elements, it must:
        - use one line per element, and
        - include the corresponding index of the array.
    3. This is the expected format:

        ```
        <HEADER>
        <index #1>: <element #1>
        <index #2>: <element #2>
        ...
        ```

    4. For example:
        - For the following code:

            ```
            procedure Test is
               A : Int_Array (1 .. 2) := (1, 5);
            begin
               Display_Int_Array ("Elements of A", A);;
            end Test;
            ```

        - The output is:

            ```
            Elements of A
             1:  1
             2:  5
            ```

2. These are the formal parameters of the procedure:
    1. a range type `T_Range` for the array;
    2. a formal type `T_Element` for the elements of the array;

- This type must be declared in such a way that it can be mapped to any type in the instantiation — including record types.

3. an array type T_Array using the T_Range and T_Element types;
4. a function Image that converts a variable of T_Element type to a **String**.

Listing 2747: display_array.ads

```
generic
procedure Display_Array (Header : String;
                         A      : T_Array);
```

Listing 2748: display_array.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Display_Array (Header : String;
                         A      : T_Array) is
begin
   null;
end Display_Array;
```

Listing 2749: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Display_Array;

procedure Main is
   type Test_Case_Index is (Int_Array_Chk,
                            Point_Array_Chk);

   procedure Test_Int_Array is
      type Int_Array is array (Positive range <>) of Integer;

      procedure Display_Int_Array is new
        Display_Array (T_Range => Positive,
                       T_Element => Integer,
                       T_Array   => Int_Array,
                       Image     => Integer'Image);

      A : constant Int_Array (1 .. 5) := (1, 2, 5, 7, 10);
   begin
      Display_Int_Array ("Integers", A);
   end Test_Int_Array;

   procedure Test_Point_Array is
      type Point is record
         X : Float;
         Y : Float;
      end record;

      type Point_Array is array (Natural range <>) of Point;

      function Image (P : Point) return String is
      begin
         return "(" & Float'Image (P.X)
           & ", " & Float'Image (P.Y) & ")";
      end Image;

```

(continues on next page)

(continued from previous page)

```
      procedure Display_Point_Array is new
        Display_Array (T_Range   => Natural,
                       T_Element => Point,
                       T_Array   => Point_Array,
                       Image     => Image);

      A : constant Point_Array (0 .. 3) := ((1.0, 0.5), (2.0, -0.5),
                                            (5.0, 2.0), (-0.5, 2.0));
   begin
      Display_Point_Array ("Points", A);
   end Test_Point_Array;

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Int_Array_Chk =>
            Test_Int_Array;
         when Point_Array_Chk =>
            Test_Point_Array;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

125.2 Average of Array of Float

Goal: create a generic function that calculates the average of an array of floating-point elements.

Steps:

1. Declare and implement the generic function `Average`.

Requirements:

1. Generic function `Average` calculates the average of an array containing floating-point values of arbitrary precision.
2. Generic function `Average` must contain the following formal parameters:
    1. a range type `T_Range` for the array;
    2. a formal type `T_Element` that can be mapped to floating-point types of arbitrary precision;
    3. an array type `T_Array` using `T_Range` and `T_Element`;

Remarks:

1. You should use the `Float` type for the accumulator.

Listing 2750: average.ads

```
generic
function Average (A : T_Array) return T_Element;
```

Listing 2751: average.adb

```
function Average (A : T_Array) return T_Element is
begin
   return 0.0;
end Average;
```

Listing 2752: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Average;

procedure Main is
   type Test_Case_Index is (Float_Array_Chk,
                            Digits_7_Float_Array_Chk);

   procedure Test_Float_Array is
      type Float_Array is array (Positive range <>) of Float;

      function Average_Float is new
        Average (T_Range   => Positive,
                 T_Element => Float,
                 T_Array   => Float_Array);

      A : constant Float_Array (1 .. 5) := (1.0, 3.0, 5.0, 7.5, -12.5);
   begin
      Put_Line ("Average: " & Float'Image (Average_Float (A)));
   end Test_Float_Array;

   procedure Test_Digits_7_Float_Array is
      type Custom_Float is digits 7 range 0.0 .. 1.0;

      type Float_Array is
        array (Integer range <>) of Custom_Float;

      function Average_Float is new
        Average (T_Range   => Integer,
                 T_Element => Custom_Float,
                 T_Array   => Float_Array);

      A : constant Float_Array (-1 .. 3) := (0.5, 0.0, 1.0, 0.6, 0.5);
   begin
      Put_Line ("Average: "
                & Custom_Float'Image (Average_Float (A)));
   end Test_Digits_7_Float_Array;

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Float_Array_Chk =>
            Test_Float_Array;
         when Digits_7_Float_Array_Chk =>
            Test_Digits_7_Float_Array;
      end case;
```

(continues on next page)

(continued from previous page)

```
48    end Check;
49
50 begin
51    if Argument_Count < 1 then
52       Put_Line ("ERROR: missing arguments! Exiting...");
53       return;
54    elsif Argument_Count > 1 then
55       Put_Line ("Ignoring additional arguments...");
56    end if;
57
58    Check (Test_Case_Index'Value (Argument (1)));
59 end Main;
```

125.3 Average of Array of Any Type

Goal: create a generic function that calculates the average of an array of elements of any arbitrary type.

Steps:

1. Declare and implement the generic function `Average`.
2. Implement the test procedure `Test_Item`.
    1. Declare the `F_IO` package.
    2. Implement the `Get_Total` function for the `Item` type.
    3. Implement the `Get_Price` function for the `Item` type.
    4. Declare the `Average_Total` function.
    5. Declare the `Average_Price` function.

Requirements:

1. Generic function `Average` calculates the average of an array containing elements of any arbitrary type.
2. Generic function `Average` has the same formal parameters as in the previous exercise, except for:
    1. `T_Element`, which is now a formal type that can be mapped to any arbitrary type.
    2. `To_Float`, which is an *additional* formal parameter.
        - `To_Float` is a function that converts the arbitrary element of `T_Element` type to the **`Float`** type.
3. Procedure `Test_Item` is used to test the generic `Average` procedure for a record type (`Item`).
    1. Record type `Item` contains the `Quantity` and `Price` components.
4. The following functions have to implemented to be used for the formal `To_Float` function parameter:
    1. For the `Decimal` type, the function is pretty straightforward: it simply returns the floating-point value converted from the decimal type.
    2. For the `Item` type, two functions must be created to convert to floating-point type:
        1. `Get_Total`, which returns the multiplication of the quantity and the price components of the `Item` type;
        2. `Get_Price`, which returns just the price.

5. The generic function Average must be instantiated as follows:
    1. For the Item type, you must:
        1. declare the Average_Total function (as an instance of Average) using the Get_Total for the To_Float parameter;
        2. declare the Average_Price function (as an instance of Average) using the Get_Price for the To_Float parameter.
6. You must use the Put procedure from Ada.Text_IO.Float_IO.
    1. The generic standard package Ada.Text_IO.Float_IO must be instantiated as F_IO in the test procedures.
    2. This is the specification of the Put procedure, as described in the appendix A.10.9 of the Ada Reference Manual:

```
procedure Put(Item : in Num;
              Fore : in Field := Default_Fore;
              Aft  : in Field := Default_Aft;
              Exp  : in Field := Default_Exp);
```

    3. This is the expected format when calling Put from Float_IO:

Function	Fore	Aft	Exp
Test_Item	3	2	0

Remarks:

1. In this exercise, you'll abstract the Average function from the previous exercises a step further.
    1. In this case, the function shall be able to calculate the average of any arbitrary type — including arrays containing elements of record types.
    2. Since record types can be composed by many components of different types, we need to provide a way to indicate which component (or components) of the record will be used when calculating the average of the array.
    3. This problem is solved by specifying a To_Float function as a formal parameter, which converts the arbitrary element of T_Element type to the **Float** type.
    4. In the implementation of the Average function, we use the To_Float function and calculate the average using a floating-point variable.

Listing 2753: average.ads

```
generic
function Average (A : T_Array) return Float;
```

Listing 2754: average.adb

```
function Average (A : T_Array) return Float is
begin
   null;
end Average;
```

Listing 2755: test_item.ads

```
procedure Test_Item;
```

Listing 2756: test_item.adb

```
with Ada.Text_IO;      use Ada.Text_IO;

with Average;

procedure Test_Item is
   type Amount is delta 0.01 digits 12;

   type Item is record
      Quantity : Natural;
      Price    : Amount;
   end record;

   type Item_Array is
     array (Positive range <>) of Item;

   A : constant Item_Array (1 .. 4)
     := ((Quantity =>  5,   Price => 10.00),
         (Quantity => 80,   Price =>  2.50),
         (Quantity => 40,   Price =>  5.00),
         (Quantity => 20,   Price => 12.50));

begin
   Put ("Average per item & quantity: ");
   F_IO.Put (Average_Total (A));
   New_Line;

   Put ("Average price:               ");
   F_IO.Put (Average_Price (A));
   New_Line;
end Test_Item;
```

Listing 2757: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;

   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

125.4 Generic list

Goal: create a system based on a generic list to add and displays elements.

Steps:

1. Declare and implement the generic package `Gen_List`.
    1. Implement the `Init` procedure.
    2. Implement the `Add` procedure.
    3. Implement the `Display` procedure.

Requirements:

1. Generic package `Gen_List` must have the following subprograms:
    1. Procedure `Init` initializes the list.
    2. Procedure `Add` adds an item to the list.
        1. This procedure must contain a `Status` output parameter that is set to **`False`** when the list was full — i.e. if the procedure failed while trying to add the item;
    3. Procedure `Display` displays the complete list.
        1. This includes the *name* of the list and its elements — using one line per element.
        2. This is the expected format:

```
<NAME>
<element #1>
<element #2>
...
```

2. Generic package `Gen_List` has these formal parameters:
    1. an arbitrary formal type `Item`;
    2. an unconstrained array type `Items` of `Item` element with positive range;
    3. the `Name` parameter containing the name of the list;
        - This must be a formal input object of **`String`** type.
        - It must be used in the `Display` procedure.
    4. an actual array `List_Array` to store the list;
        - This must be a formal **`in out`** object of `Items` type.
    5. the variable `Last` to store the index of the last element;
        - This must be a formal **`in out`** object of **`Natural`** type.
    6. a procedure `Put` for the `Item` type.
        - This procedure is used in the `Display` procedure to display individual elements of the list.
3. The test procedure `Test_Int` is used to test a list of elements of **`Integer`** type.
4. For both test procedures, you must:
    1. add missing type declarations;
    2. declare and implement a `Put` procedure for individual elements of the list;
    3. declare instances of the `Gen_List` package.
        - For the `Test_Int` procedure, declare the `Int_List` package.

Remarks:

1. In previous labs, you've been implementing lists for a variety of types.
   - The *List of Names* exercise from the *Arrays* (page 2351) labs is an example.
   - In this exercise, you have to abstract those implementations to create the generic `Gen_List` package.

Listing 2758: gen_list.ads

```
generic
package Gen_List is

   procedure Init;

   procedure Add (I      :     Item;
                  Status : out Boolean);

   procedure Display;

end Gen_List;
```

         when Int_Chk =>
            Test_Int;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

SIX

EXCEPTIONS

126.1 Uninitialized Value

Goal: implement an enumeration to avoid the use of uninitialized values.

Steps:

1. Implement the `Options` package.
    1. Declare the `Option` enumeration type.
    2. Declare the `Uninitialized_Value` exception.
    3. Implement the `Image` function.

Requirements:

1. Enumeration `Option` contains:
    1. the `Uninitialized` value, and
    2. the actual options:
        - `Option_1`,
        - `Option_2`,
        - `Option_3`.
2. Function `Image` returns a string for the `Option` type.
    1. In case the argument to `Image` is `Uninitialized`, the function must raise the `Uninitialized_Value` exception.

Remarks:

1. In this exercise, we employ exceptions as a mechanism to avoid the use of uninitialized values for a certain type.

Listing 2763: options.ads

```
package Options is

   --  Declare the Option enumeration type!
   type Option is null record;

   function Image (O : Option) return String;

end Options;
```

Listing 2764: options.adb

```
package body Options is

   function Image (O : Option) return String is
   begin
      return "";
   end Image;

end Options;
```

Listing 2765: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;
with Ada.Exceptions;   use Ada.Exceptions;

with Options;          use Options;

procedure Main is
   type Test_Case_Index is
     (Options_Chk);

   procedure Check (TC : Test_Case_Index) is

      procedure Check (O : Option) is
      begin
         Put_Line (Image (O));
      exception
         when E : Uninitialized_Value =>
            Put_Line (Exception_Message (E));
      end Check;

   begin
      case TC is
      when Options_Chk =>
         for O in Option loop
            Check (O);
         end loop;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

126.2 Numerical Exception

Goal: handle numerical exceptions in a test procedure.

Steps:

1. Add exception handling to the `Check_Exception` procedure.

Requirements:

1. The test procedure `Num_Exception_Test` from the `Tests` package below must be used in the implementation of `Check_Exception`.
2. The `Check_Exception` procedure must be extended to handle exceptions as follows:
    1. If the exception raised by `Num_Exception_Test` is `Constraint_Error`, the procedure must display the message "Constraint_Error detected!" to the user.
    2. Otherwise, it must display the message associated with the exception.

Remarks:

1. You can use the `Exception_Message` function to retrieve the message associated with an exception.

Listing 2766: tests.ads

```
package Tests is

   type Test_ID is (Test_1, Test_2);

   Custom_Exception : exception;

   procedure Num_Exception_Test (ID : Test_ID);

end Tests;
```

Listing 2767: tests.adb

```
package body Tests is

   pragma Warnings (Off, "variable ""C"" is assigned but never read");

   procedure Num_Exception_Test (ID : Test_ID) is
      A, B, C : Integer;
   begin
      case ID is
         when Test_1 =>
            A := Integer'Last;
            B := Integer'Last;
            C := A + B;
         when Test_2 =>
            raise Custom_Exception with "Custom_Exception raised!";
      end case;
   end Num_Exception_Test;

   pragma Warnings (On, "variable ""C"" is assigned but never read");

end Tests;
```

Listing 2768: check_exception.adb

```
with Tests; use Tests;

procedure Check_Exception (ID : Test_ID) is
begin
   Num_Exception_Test (ID);
end Check_Exception;
```

Listing 2769: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;
```

(continues on next page)

(continued from previous page)

```
with Ada.Exceptions;   use Ada.Exceptions;

with Tests;            use Tests;
with Check_Exception;

procedure Main is
   type Test_Case_Index is
     (Exception_1_Chk,
      Exception_2_Chk);

   procedure Check (TC : Test_Case_Index) is

      procedure Check_Handle_Exception (ID : Test_ID) is
      begin
         Check_Exception (ID);
      exception
         when Constraint_Error =>
            Put_Line ("Constraint_Error"
                      & " (raised by Check_Exception) detected!");
         when E : others =>
            Put_Line (Exception_Name (E)
                      & " (raised by Check_Exception) detected!");
      end Check_Handle_Exception;

   begin
      case TC is
      when Exception_1_Chk =>
         Check_Handle_Exception (Test_1);
      when Exception_2_Chk =>
         Check_Handle_Exception (Test_2);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

126.3 Re-raising Exceptions

Goal: make use of exception re-raising in a test procedure.

Steps:

1. Declare new exception: `Another_Exception`.
2. Add exception re-raise to the `Check_Exception` procedure.

Requirements:

1. Exception `Another_Exception` must be declared in the `Tests` package.
2. Procedure `Check_Exception` must be extended to *re-raise* any exception. When an exception is detected, the procedure must:
    1. display a user message (as implemented in the previous exercise), and then

2. Raise or *re-raise* exception depending on the exception that is being handled:
    1. In case of `Constraint_Error` exception, *re-raise* the exception.
    2. In all other cases, raise `Another_Exception`.

Remarks:

1. In this exercise, you should extend the implementation of the `Check_Exception` procedure from the previous exercise.
    1. Naturally, you can use the code for the `Check_Exception` procedure from the previous exercise as a starting point.

Listing 2770: tests.ads

```
package Tests is

   type Test_ID is (Test_1, Test_2);

   Custom_Exception : exception;

   procedure Num_Exception_Test (ID : Test_ID);

end Tests;
```

Listing 2771: tests.adb

```
package body Tests is

   pragma Warnings (Off, "variable ""C"" is assigned but never read");

   procedure Num_Exception_Test (ID : Test_ID) is
      A, B, C : Integer;
   begin
      case ID is
         when Test_1 =>
            A := Integer'Last;
            B := Integer'Last;
            C := A + B;
         when Test_2 =>
            raise Custom_Exception with "Custom_Exception raised!";
      end case;
   end Num_Exception_Test;

   pragma Warnings (On, "variable ""C"" is assigned but never read");

end Tests;
```

procedure Check_Exception (ID : Test_ID) is
begin
   Num_Exception_Test (ID);
end Check_Exception;
```

Listing 2774: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;
with Ada.Exceptions;   use Ada.Exceptions;

with Tests;            use Tests;
with Check_Exception;

procedure Main is
   type Test_Case_Index is
     (Exception_1_Chk,
      Exception_2_Chk);

   procedure Check (TC : Test_Case_Index) is

      procedure Check_Handle_Exception (ID : Test_ID) is
      begin
         Check_Exception (ID);
      exception
         when Constraint_Error =>
            Put_Line ("Constraint_Error"
                      & " (raised by Check_Exception) detected!");
         when E : others =>
            Put_Line (Exception_Name (E)
                      & " (raised by Check_Exception) detected!");
      end Check_Handle_Exception;

   begin
      case TC is
      when Exception_1_Chk =>
         Check_Handle_Exception (Test_1);
      when Exception_2_Chk =>
         Check_Handle_Exception (Test_2);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

SEVEN

TASKING

127.1 Display Service

Goal: create a simple service that displays messages to the user.

Steps:

1. Implement the `Display_Services` package.
    1. Declare the task type `Display_Service`.
    2. Implement the `Display` entry for strings.
    3. Implement the `Display` entry for integers.

Requirements:

1. Task type `Display_Service` uses the `Display` entry to display messages to the user.
2. There are two versions of the `Display` entry:
    1. One that receives messages as a string parameter.
    2. One that receives messages as an `Integer` parameter.
3. When a message is received via a `Display` entry, it must be displayed immediately to the user.

Listing 2775: display_services.ads

```
package Display_Services is

end Display_Services;
```

Listing 2776: display_services.adb

```
package body Display_Services is

end Display_Services;
```

Listing 2777: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Display_Services; use Display_Services;

procedure Main is
   type Test_Case_Index is (Display_Service_Chk);

   procedure Check (TC : Test_Case_Index) is
      Display : Display_Service;
```

(continues on next page)

(continued from previous page)

```
   begin
      case TC is
         when Display_Service_Chk =>
            Display.Display ("Hello");
            delay 0.5;
            Display.Display ("Hello again");
            delay 0.5;
            Display.Display (55);
            delay 0.5;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

127.2 Event Manager

Goal: implement a simple event manager.

Steps:

1. Implement the `Event_Managers` package.
    1. Declare the task type `Event_Manager`.
    2. Implement the `Start` entry.
    3. Implement the `Event` entry.

Requirements:

1. The event manager has a similar behavior as an alarm
    1. The sole purpose of this event manager is to display the event ID at the correct time.
    2. After the event ID is displayed, the task must finish.
2. The event manager (`Event_Manager` type) must have two entries:
    1. `Start`, which starts the event manager with an event ID;
    2. `Event`, which delays the task until a certain time and then displays the event ID as a user message.
3. The format of the user message displayed by the event manager is `Event #<event_id>`.
    1. You should use `Natural'Image` to display the ID (as indicated in the body of the `Event_Managers` package below).

Remarks:

1. In the `Start` entry, you can use the **`Natural`** type for the ID.
2. In the `Event` entry, you should use the `Time` type from the `Ada.Real_Time` package for the time parameter.

3. Note that the test application below creates an array of event managers with different delays.

Listing 2778: event_managers.ads

```
package Event_Managers is

end Event_Managers;
```

Listing 2779: event_managers.adb

```
package body Event_Managers is

      --   Don't forget to display the event ID:
      --
      --   Put_Line ("Event #" & Natural'Image (Event_ID));

end Event_Managers;
```

Listing 2780: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Event_Managers;   use Event_Managers;
with Ada.Real_Time;    use Ada.Real_Time;

procedure Main is
   type Test_Case_Index is (Event_Manager_Chk);

   procedure Check (TC : Test_Case_Index) is
      Ev_Mng : array (1 .. 5) of Event_Manager;
   begin
      case TC is
         when Event_Manager_Chk =>
            for I in Ev_Mng'Range loop
               Ev_Mng (I).Start (I);
            end loop;
            Ev_Mng (1).Event (Clock + Seconds (5));
            Ev_Mng (2).Event (Clock + Seconds (3));
            Ev_Mng (3).Event (Clock + Seconds (1));
            Ev_Mng (4).Event (Clock + Seconds (2));
            Ev_Mng (5).Event (Clock + Seconds (4));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

127.3 Generic Protected Queue

Goal: create a queue container using a protected type.

Steps:

1. Implement the generic package `Gen_Queues`.
    1. Declare the protected type `Queue`.
    2. Implement the `Empty` function.
    3. Implement the `Full` function.
    4. Implement the `Push` entry.
    5. Implement the `Pop` entry.

Requirements:

1. These are the formal parameters for the generic package `Gen_Queues`:
    1. a formal modular type;
        - This modular type should be used by the `Queue` to declare an array that stores the elements of the queue.
        - The modulus of the modular type must correspond to the maximum number of elements of the queue.
    2. the data type of the elements of the queue.
        - Select a formal parameter that allows you to store elements of any data type in the queue.
2. These are the operations of the `Queue` type:
    1. Function `Empty` indicates whether the queue is empty.
    2. Function `Full` indicates whether the queue is full.
    3. Entry `Push` stores an element in the queue.
    4. Entry `Pop` removes an element from the queue and returns the element via output parameter.

Remarks:

1. In this exercise, we create a queue container by declaring and implementing a protected type (`Queue`) as part of a generic package (`Gen_Queues`).
2. As a bonus exercise, you can analyze the body of the `Queue_Tests` package and understand how the `Queue` type is used there.
    1. In particular, the procedure `Concurrent_Test` implements two tasks: `T_Producer` and `T_Consumer`. They make use of the queue concurrently.

Listing 2781: gen_queues.ads

```
package Gen_Queues is

end Gen_Queues;
```

Listing 2782: gen_queues.adb

```
package body Gen_Queues is

end Gen_Queues;
```

Listing 2783: queue_tests.ads

```
package Queue_Tests is

   procedure Simple_Test;

   procedure Concurrent_Test;

end Queue_Tests;
```

Listing 2784: queue_tests.adb

```
with Ada.Text_IO; use Ada.Text_IO;

with Gen_Queues;

package body Queue_Tests is

   Max : constant := 10;
   type Queue_Mod is mod Max;

   procedure Simple_Test is
      package Queues_Float is new Gen_Queues (Queue_Mod, Float);

      Q_F : Queues_Float.Queue;
      V   : Float;
   begin
      V := 10.0;
      while not Q_F.Full loop
         Q_F.Push (V);
         V := V + 1.5;
      end loop;

      while not Q_F.Empty loop
         Q_F.Pop (V);
         Put_Line ("Value from queue: " & Float'Image (V));
      end loop;
   end Simple_Test;

   procedure Concurrent_Test is
      package Queues_Integer is new Gen_Queues (Queue_Mod, Integer);

      Q_I : Queues_Integer.Queue;

      task T_Producer;
      task T_Consumer;

      task body T_Producer is
         V : Integer := 100;

   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

CHAPTER

EIGHT

DESIGN BY CONTRACTS

128.1 Price Range

Goal: use predicates to indicate the correct range of prices.

Steps:

1. Complete the `Prices` package.
    1. Rewrite the type declaration of `Price`.

Requirements:

1. Type `Price` must use a predicate instead of a range.

Remarks:

1. As discussed in the course, ranges are a form of contract.
    1. For example, the subtype `Price` below indicates that a value of this subtype must always be positive:

        ```
        subtype Price is Amount range 0.0 .. Amount'Last;
        ```

    2. Interestingly, you can replace ranges by predicates, which is the goal of this exercise.

Listing 2786: prices.ads

```
package Prices is

   type Amount is delta 10.0 ** (-2) digits 12;

   subtype Price is Amount range 0.0 .. Amount'Last;

end Prices;
```

Listing 2787: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;
with System.Assertions; use System.Assertions;

with Prices;            use Prices;

procedure Main is

   type Test_Case_Index is
     (Price_Range_Chk);

   procedure Check (TC : Test_Case_Index) is
```

(continues on next page)

(continued from previous page)

```
13
14       procedure Check_Range (A : Amount) is
15          P : constant Price := A;
16       begin
17          Put_Line ("Price: " & Price'Image (P));
18       end Check_Range;
19
20    begin
21       case TC is
22       when Price_Range_Chk =>
23          Check_Range (-2.0);
24       end case;
25    exception
26       when Constraint_Error =>
27          Put_Line ("Constraint_Error detected (NOT as expected).");
28       when Assert_Failure =>
29          Put_Line ("Assert_Failure detected (as expected).");
30    end Check;
31
32 begin
33    if Argument_Count < 1 then
34       Put_Line ("ERROR: missing arguments! Exiting...");
35       return;
36    elsif Argument_Count > 1 then
37       Put_Line ("Ignoring additional arguments...");
38    end if;
39
40    Check (Test_Case_Index'Value (Argument (1)));
41 end Main;
```

128.2 Pythagorean Theorem: Predicate

Goal: use the Pythagorean theorem as a predicate.

Steps:

1. Complete the `Triangles` package.
    1. Add a predicate to the `Right_Triangle` type.

Requirements:

1. The `Right_Triangle` type must use the Pythagorean theorem as a predicate to ensure that its components are consistent.

Remarks:

1. As you probably remember, the Pythagoras' theorem[603] states that the square of the hypotenuse of a right triangle is equal to the sum of the squares of the other two sides.

Listing 2788: triangles.ads

```
1  package Triangles is
2
3     subtype Length is Integer;
4
5     type Right_Triangle is record
6        H      : Length := 0;
7        --  Hypotenuse
8        C1, C2 : Length := 0;
```

with System.Assertions; use System.Assertions;

with Triangles;         use Triangles;
with Triangles.IO;      use Triangles.IO;

procedure Main is

   type Test_Case_Index is
     (Triangle_8_6_Pass_Chk,
      Triangle_8_6_Fail_Chk,
      Triangle_10_24_Pass_Chk,
      Triangle_10_24_Fail_Chk,
      Triangle_18_24_Pass_Chk,
      Triangle_18_24_Fail_Chk);

   procedure Check (TC : Test_Case_Index) is

      procedure Check_Triangle (H, C1, C2 : Length) is
         T : Right_Triangle;
      begin
         T := Init (H, C1, C2);
         Put_Line (Image (T));
      exception
         when Constraint_Error =>
            Put_Line ("Constraint_Error detected (NOT as expected).");
         when Assert_Failure =>
            Put_Line ("Assert_Failure detected (as expected).");
      end Check_Triangle;
```

(continues on next page)

(continued from previous page)

```
31
32    begin
33       case TC is
34          when Triangle_8_6_Pass_Chk   => Check_Triangle (10,  8,  6);
35          when Triangle_8_6_Fail_Chk   => Check_Triangle (12,  8,  6);
36          when Triangle_10_24_Pass_Chk => Check_Triangle (26, 10, 24);
37          when Triangle_10_24_Fail_Chk => Check_Triangle (12, 10, 24);
38          when Triangle_18_24_Pass_Chk => Check_Triangle (30, 18, 24);
39          when Triangle_18_24_Fail_Chk => Check_Triangle (32, 18, 24);
40       end case;
41    end Check;
42
43 begin
44    if Argument_Count < 1 then
45       Put_Line ("ERROR: missing arguments! Exiting...");
46       return;
47    elsif Argument_Count > 1 then
48       Put_Line ("Ignoring additional arguments...");
49    end if;
50
51    Check (Test_Case_Index'Value (Argument (1)));
52 end Main;
```

128.3 Pythagorean Theorem: Precondition

Goal: use the Pythagorean theorem as a precondition.

Steps:

1. Complete the `Triangles` package.
    1. Add a precondition to the `Init` function.

Requirements:

1. The `Init` function must use the Pythagorean theorem as a precondition to ensure that the input values are consistent.

Remarks:

1. In this exercise, you'll work again with the `Right_Triangle` type.
    1. This time, your job is to use a precondition instead of a predicate.
    2. The precondition is applied to the `Init` function, not to the `Right_Triangle` type.

Listing 2792: triangles.ads

```
1  package Triangles is
2
3     subtype Length is Integer;
4
5     type Right_Triangle is record
6        H      : Length := 0;
7        --  Hypotenuse
8        C1, C2 : Length := 0;
9        --  Catheti / legs
10    end record;
11
12    function Init (H, C1, C2 : Length) return Right_Triangle is
13      ((H, C1, C2));
14
15 end Triangles;
```

      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

128.4 Pythagorean Theorem: Postcondition

Goal: use the Pythagorean theorem as a postcondition.

Steps:

1. Complete the `Triangles` package.
    1. Add a postcondition to the `Init` function.

Requirements:

1. The `Init` function must use the Pythagorean theorem as a postcondition to ensure that the returned object is consistent.

Remarks:

1. In this exercise, you'll work again with the `Triangles` package.
    1. This time, your job is to apply a postcondition instead of a precondition to the `Init` function.

Listing 2796: triangles.ads

```
package Triangles is

   subtype Length is Integer;

   type Right_Triangle is record
      H      : Length := 0;
      --  Hypotenuse
      C1, C2 : Length := 0;
      --  Catheti / legs
   end record;

   function Init (H, C1, C2 : Length) return Right_Triangle is
     ((H, C1, C2));

end Triangles;
```

Listing 2797: triangles-io.ads

```
package Triangles.IO is

(continued from previous page)

```
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

128.5 Pythagorean Theorem: Type Invariant

Goal: use the Pythagorean theorem as a type invariant.

Steps:

1. Complete the `Triangles` package.
    1. Add a type invariant to the `Right_Triangle` type.

Requirements:

1. `Right_Triangle` is a private type.
    1. It must use the Pythagorean theorem as a type invariant to ensure that its encapsulated components are consistent.

Remarks:

1. In this exercise, `Right_Triangle` is declared as a private type.
    1. In this case, we use a type invariant for `Right_Triangle` to check the Pythagorean theorem.
2. As a bonus, after completing the exercise, you may analyze the effect that default values have on type invariants.
    1. For example, the declaration of `Right_Triangle` uses zero as the default values of the three triangle lengths.
    2. If you replace those default values with `Length'Last`, you'll get different results.
    3. Make sure you understand why this is happening.

Listing 2800: triangles.ads

```
package Triangles is

   subtype Length is Integer;

   type Right_Triangle is private;

   function Init (H, C1, C2 : Length) return Right_Triangle;

private

   type Right_Triangle is record
      H      : Length := 0;
      --  Hypotenuse
      C1, C2 : Length := 0;
      --  Catheti / legs
   end record;

   function Init (H, C1, C2 : Length) return Right_Triangle is
     ((H, C1, C2));

end Triangles;
```

Listing 2801: triangles-io.ads

      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

128.6 Primary Color

Goal: extend a package for HTML colors so that it can handle primary colors.

Steps:

1. Complete the `Color_Types` package.
    1. Declare the `HTML_RGB_Color` subtype.
    2. Implement the `To_Int_Color` function.

Requirements:

1. The `HTML_Color` type is an enumeration that contains a list of HTML colors.
2. The `To_RGB_Lookup_Table` array implements a lookup-table to convert the colors into a hexadecimal value using RGB color components (i.e. `Red`, `Green` and `Blue`)
3. Function `To_Int_Color` extracts one of the RGB components of an HTML color and returns its hexadecimal value.
    1. The function has two parameters:
        - First parameter is the HTML color (`HTML_Color` type).
        - Second parameter indicates which RGB component is to be extracted from the HTML color (`HTML_RGB_Color` subtype).
    2. For example, if we call `To_Int_Color (Salmon, Red)`, the function returns `#FA`,
        - This is the hexadecimal value of the red component of the `Salmon` color.
        - You can find further remarks below about this color as an example.
4. The `HTML_RGB_Color` subtype is limited to the primary RGB colors components (i.e. `Red`, `Green` and `Blue`).
    1. This subtype is used to select the RGB component in calls to `To_Int_Color`.
    2. You must use a predicate in the type declaration.

Remarks:

1. In this exercise, we reuse the code of the `Colors: Lookup-Table` exercise from the *Arrays* (page 2351) labs.
2. These are the hexadecimal values of the colors that we used in the original exercise:

Color	Value
Salmon	#FA8072
Firebrick	#B22222
Red	#FF0000
Darkred	#8B0000
Lime	#00FF00
Forestgreen	#228B22
Green	#008000
Darkgreen	#006400
Blue	#0000FF
Mediumblue	#0000CD
Darkblue	#00008B

3. You can extract the hexadecimal value of each primary color by splitting the values from the table above into three hexadecimal values with two digits each.
   - For example, the hexadecimal value of `Salmon` is `#FA8072`, where:
     - the first part of this hexadecimal value (`#FA`) corresponds to the red component,
     - the second part (`#80`) corresponds to the green component, and
     - the last part (`#72`) corresponds to the blue component.

Listing 2804: color_types.ads

```
package Color_Types is

   type HTML_Color is
     (Salmon,
      Firebrick,
      Red,
      Darkred,
      Lime,
      Forestgreen,
      Green,
      Darkgreen,
      Blue,
      Mediumblue,
      Darkblue);

   subtype Int_Color is Integer range 0 .. 255;

   function Image (I : Int_Color) return String;

   type RGB is record
      Red   : Int_Color;
      Green : Int_Color;
      Blue  : Int_Color;
   end record;

   function To_RGB (C : HTML_Color) return RGB;

   function Image (C : RGB) return String;

   type HTML_Color_RGB_Array is array (HTML_Color) of RGB;

   To_RGB_Lookup_Table : constant HTML_Color_RGB_Array

CHAPTER

NINE

OBJECT-ORIENTED PROGRAMMING

129.1 Simple type extension

Goal: work with type extensions using record types containing numeric components.

Steps:

1. Implement the `Type_Extensions` package.
    1. Declare the record type `T_Float`.
    2. Declare the record type `T_Mixed`
    3. Implement the `Init` function for the `T_Float` type with a floating-point input parameter.
    4. Implement the `Init` function for the `T_Float` type with an integer input parameter.
    5. Implement the `Image` function for the `T_Float` type.
    6. Implement the `Init` function for the `T_Mixed` type with a floating-point input parameter.
    7. Implement the `Init` function for the `T_Mixed` type with an integer input parameter.
    8. Implement the `Image` function for the `T_Mixed` type.

Requirements:

1. Record type `T_Float` contains the following component:
    1. `F`, a floating-point type.
2. Record type `T_Mixed` is derived from the `T_Float` type.
    1. `T_Mixed` extends `T_Float` with the following component:
        1. `I`, an integer component.
    2. Both components must be numerically *synchronized*:
        - For example, if the floating-point component contains the value 2.0, the value of the integer component must be 2.
        - In order to simplify the implementation, you can simply use `Integer (F)` to convert a floating-point variable F to integer.
3. Function `Init` returns an object of the corresponding type (`T_Float` or `T_Mixed`).
    1. For each type, two versions of `Init` must be declared:
        1. one with a floating-point input parameter,
        2. another with an integer input parameter.
    2. The parameter to `Init` is used to initialize the record components.
4. Function `Image` returns a string for the components of the record type.

1. In case of the Image function for the T_Float type, the string must have the format "{ F => <float value> }".
   - For example, the call Image (T_Float'(Init (8.0)))) should return the string "{ F => 8.00000E+00 }".
2. In case of the Image function for the T_Mixed type, the string must have the format "{ F => <float value>, I => <integer value> }".
   - For example, the call Image (T_Mixed'(Init (8.0)))) should return the string "{ F => 8.00000E+00, I => 8 }".

Listing 2807: type_extensions.ads

```
package Type_Extensions is

   --  Create declaration of T_Float type!
   type T_Float is null record;

   --  function Init ...

   --  function Image ...

   --  Create declaration of T_Mixed type!
   type T_Mixed is null record;

end Type_Extensions;
```

Listing 2808: type_extensions.adb

```
package body Type_Extensions is

end Type_Extensions;
```

Listing 2809: main.adb

```
with Ada.Command_Line; use Ada.Command_Line;
with Ada.Text_IO;      use Ada.Text_IO;

with Type_Extensions;  use Type_Extensions;

procedure Main is

   type Test_Case_Index is
     (Type_Extension_Chk);

   procedure Check (TC : Test_Case_Index) is
      F1, F2 : T_Float;
      M1, M2 : T_Mixed;
   begin
      case TC is
      when Type_Extension_Chk =>
         F1 := Init (2.0);
         F2 := Init (3);
         M1 := Init (4.0);
         M2 := Init (5);

         if M2 in T_Float'Class then
           Put_Line ("T_Mixed is in T_Float'Class as expected");
         end if;

         Put_Line ("F1: " & Image (F1));
```

(continues on next page)

(continued from previous page)

```
         Put_Line ("F2: " & Image (F2));
         Put_Line ("M1: " & Image (M1));
         Put_Line ("M2: " & Image (M2));
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

129.2 Online Store

Goal: create an online store for the members of an association.

Steps:

1. Implement the `Online_Store` package.
    1. Declare the `Member` type.
    2. Declare the `Full_Member` type.
    3. Implement the `Get_Status` function for the `Member` type.
    4. Implement the `Get_Price` function for the `Member` type.
    5. Implement the `Get_Status` function for the `Full_Member` type.
    6. Implement the `Get_Price` function for the `Full_Member` type.
2. Implement the `Online_Store.Tests` child package.
    1. Implement the `Simple_Test` procedure.

Requirements:

1. Package `Online_Store` implements an online store application for the members of an association.
    1. In this association, members can have one of the following status:
        - associate member, or
        - full member.
2. Function `Get_Price` returns the correct price of an item.
    1. Associate members must pay the full price when they buy items from the online store.
    2. Full members can get a discount.
        1. The discount rate can be different for each full member — depending on factors that are irrelevant for this exercise.
3. Package `Online_Store` has following types:
    1. `Percentage` type, which represents a percentage ranging from 0.0 to 1.0.
    2. `Member` type for associate members containing following components:

- `Start`, which indicates the starting year of the membership.
  - This information is common for both associate and full members.
  - You can use the `Year_Number` type from the standard `Ada.Calendar` package for this component.

3. `Full_Member` type for full members.
   1. This type must extend the `Member` type above.
   2. It contains the following additional component:
      - `Discount`, which indicates the discount rate that the full member gets in the online store.
        - This component must be of `Percentage` type.

4. For the `Member` and `Full_Member` types, you must implement the following functions:
   1. `Get_Status`, which returns a string with the membership status.
      - The string must be `"Associate Member"` or `"Full Member"`, respectively.
   2. `Get_Price`, which returns the *adapted price* of an item — indicating the actual due amount.
      - For example, for a full member with a 10% discount rate, the actual due amount of an item with a price of 100.00 is 90.00.
      - Associated members don't get a discount, so they always pay the full price.
5. Procedure `Simple_Test` (from the `Online_Store.Tests` package) is used for testing.
   1. Based on a list of members that bought on the online store and the corresponding full price of the item, `Simple_Test` must display information about each member and the actual due amount after discounts.
   2. Information about the members must be displayed in the following format:

```
Member # <number>
Status: <status>
Since:  <year>
Due Amount:  <value>
--------
```

   3. For this exercise, `Simple_Test` must use the following list:

#	Membership status	Start (year)	Discount	Full Price
1	Associate	2010	*N/A*	250.00
2	Full	1998	10.0 %	160.00
3	Full	1987	20.0 %	400.00
4	Associate	2013	*N/A*	110.00

   4. In order to pass the tests, the information displayed by a call to `Simple_Test` must conform to the format described above.
      - You can find another example in the remarks below.

Remarks:

1. In previous labs, we could have implemented a simplified version of the system described above by simply using an enumeration type to specify the membership status. For example:

```
type Member_Status is (Associate_Member, Full_Member);
```

1. In this case, the `Get_Price` function would then evaluate the membership status and adapt the item price — assuming a fixed discount rate for all full members. This could be the corresponding function declaration:

```
type Amount is delta 10.0**(-2) digits 10;

function Get_Price (M : Member_Status;
                    P : Amount) return Amount;
```

2. In this exercise, however, we'll use type extension to represent the membership status in our application.

2. For the procedure `Simple_Test`, let's consider the following list of members as an example:

#	Membership status	Start (year)	Discount	Full Price
1	Associate	2002	*N/A*	100.00
2	Full	2005	10.0 %	100.00

- For this list, the test procedure displays the following information (in this exact format):

```
Member # 1
Status: Associate Member
Since:  2002
Due Amount:  100.00
--------
Member # 2
Status: Full Member
Since:  2005
Due Amount:  90.00
--------
```

- Here, although both members had the same full price (as indicated by the last column), member #2 gets a reduced due amount of 90.00 because of the full membership status.

Listing 2810: online_store.ads

```
with Ada.Calendar; use Ada.Calendar;

package Online_Store is

   type Amount is delta 10.0**(-2) digits 10;

   subtype Percentage is Amount range 0.0 .. 1.0;

   --  Create declaration of Member type!
   --
   --  You can use Year_Number from Ada.Calendar for the membership
   --  starting year.
   --
   type Member is null record;

   function Get_Status (M : Member) return String;

   function Get_Price (M : Member;
                       P : Amount) return Amount;

   --  Create declaration of Full_Member type!
   --
```

(continues on next page)

(continued from previous page)

```
   --  Use the Percentage type for storing the membership discount.
   --
   type Full_Member is null record;

   function Get_Status (M : Full_Member) return String;

   function Get_Price (M : Full_Member;
                       P : Amount) return Amount;

end Online_Store;
```

Listing 2811: online_store.adb

```
package body Online_Store is

   function Get_Status (M : Member) return String is
     ("");

   function Get_Status (M : Full_Member) return String is
     ("");

   function Get_Price (M : Member;
                       P : Amount) return Amount is (0.0);

   function Get_Price (M : Full_Member;
                       P : Amount) return Amount is
     (0.0);

end Online_Store;
```

```

STANDARD LIBRARY: CONTAINERS

130.1 Simple todo list

Goal: implement a simple to-do list system using vectors.

Steps:

1. Implement the `Todo_Lists` package.
    1. Declare the `Todo_Item` type.
    2. Declare the `Todo_List` type.
    3. Implement the `Add` procedure.
    4. Implement the `Display` procedure.
2. `Todo_Item` type is used to store to-do items.
    1. It should be implemented as an access type to strings.
3. `Todo_List` type is the container for all to-do items.
    1. It should be implemented as a **vector**.
4. Procedure `Add` adds items (of `Todo_Item` type) to the list (of `Todo_List` type).
    1. This requires allocating a string for the access type.
5. Procedure `Display` is used to display all to-do items.
    1. It must display one item per line.

Remarks:

1. This exercise is based on the *Simple todo list* exercise from the *More About Types* (page 2369).
    1. Your goal is to rewrite that exercise using vectors instead of arrays.
    2. You may reuse the code you've already implemented as a starting point.

Listing 2815: todo_lists.ads

```
package Todo_Lists is

   type Todo_Item is access String;

   type Todo_List is null record;

   procedure Add (Todos : in out Todo_List;
                  Item  : String);

   procedure Display (Todos : Todo_List);

end Todo_Lists;
```

Listing 2816: todo_lists.adb

```
with Ada.Text_IO; use Ada.Text_IO;

package body Todo_Lists is

   procedure Add (Todos : in out Todo_List;
                  Item  : String) is
   begin
      null;
   end Add;

   procedure Display (Todos : Todo_List) is
   begin
      Put_Line ("TO-DO LIST");
   end Display;

end Todo_Lists;
```

Listing 2817: main.adb

```
with Ada.Command_Line;  use Ada.Command_Line;
with Ada.Text_IO;       use Ada.Text_IO;

with Todo_Lists;        use Todo_Lists;

procedure Main is
   type Test_Case_Index is
     (Todo_List_Chk);

   procedure Check (TC : Test_Case_Index) is
      T : Todo_List;
   begin
      case TC is
         when Todo_List_Chk =>
            Add (T, "Buy milk");
            Add (T, "Buy tea");
            Add (T, "Buy present");
            Add (T, "Buy tickets");
            Add (T, "Pay electricity bill");
            Add (T, "Schedule dentist appointment");
            Add (T, "Call sister");
            Add (T, "Revise spreasheet");
            Add (T, "Edit entry page");
            Add (T, "Select new design");
            Add (T, "Create upgrade plan");
            Display (T);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

130.2 List of unique integers

Goal: create function that removes duplicates from and orders a collection of elements.

Steps:

1. Implement package `Ops`.
    1. Declare the `Int_Array` type.
    2. Declare the `Integer_Sets` type.
    3. Implement the `Get_Unique` function that returns a set.
    4. Implement the `Get_Unique` function that returns an array of integer values.

Requirements:

1. The `Int_Array` type is an unconstrained array of positive range.
2. The `Integer_Sets` package is an instantiation of the `Ordered_Sets` package for the **`Integer`** type.
3. The `Get_Unique` function must remove duplicates from an input array of integer values and order the elements.
    1. For example:
        - if the input array contains `(7, 7, 1)`
        - the function must return `(1, 7)`.
    2. You must implement this function by using sets from the `Ordered_Sets` package.
    3. `Get_Unique` must be implemented in two versions:
        - one version that returns a set — `Set` type from the `Ordered_Sets` package.
        - one version that returns an array of integer values — `Int_Array` type.

Remarks:

1. Sets — as the one found in the generic `Ordered_Sets` package — are useful for quickly and easily creating an algorithm that removes duplicates from a list of elements.

Listing 2818: ops.ads

```
with Ada.Containers.Ordered_Sets;

package Ops is

   --  type Int_Array is ...

   --  package Integer_Sets is ...

   subtype Int_Set is Integer_Sets.Set;

   function Get_Unique (A : Int_Array) return Int_Set;

   function Get_Unique (A : Int_Array) return Int_Array;

end Ops;
```

Listing 2819: ops.adb

```
package body Ops is

   function Get_Unique (A : Int_Array) return Int_Set is
```

(continues on next page)

(continued from previous page)

```
   begin
      null;
   end Get_Unique;

   function Get_Unique (A : Int_Array) return Int_Array is
   begin
      null;
   end Get_Unique;

end Ops;
```

Listing 2820: main.adb

```
with Ada.Command_Line;        use Ada.Command_Line;
with Ada.Text_IO;             use Ada.Text_IO;

```

CHAPTER

ONE

STANDARD LIBRARY: DATES & TIMES

131.1 Holocene calendar

Goal: create a function that returns the year in the Holocene calendar.

Steps:

1. Implement the `To_Holocene_Year` function.

Requirements:

1. The `To_Holocene_Year` extracts the year from a time object (`Time` type) and returns the corresponding year for the Holocene calendar[604].
    1. For positive (AD) years, the Holocene year is calculated by adding 10,000 to the year number.

Remarks:

1. In this exercise, we don't deal with BC years.
2. Note that the year component of the `Time` type from the `Ada.Calendar` package is limited to years starting with 1901.

Listing 2821: to_holocene_year.adb

```
with Ada.Calendar; use Ada.Calendar;

function To_Holocene_Year (T : Time) return Integer is
begin
   return 0;
end To_Holocene_Year;
```

Listing 2822: main.adb

```
with Ada.Command_Line;        use Ada.Command_Line;
with Ada.Text_IO;             use Ada.Text_IO;
with Ada.Calendar;            use Ada.Calendar;

with To_Holocene_Year;

procedure Main is
   type Test_Case_Index is
     (Holocene_Chk);

   procedure Display_Holocene_Year (Y : Year_Number) is
      HY : Integer;
   begin
      HY := To_Holocene_Year (Time_Of (Y, 1, 1));
```

(continues on next page)

[604] https://en.wikipedia.org/wiki/Holocene_calendar

(continued from previous page)

```
      Put_Line ("Year (Gregorian): " & Year_Number'Image (Y));
      Put_Line ("Year (Holocene):  " & Integer'Image (HY));
   end Display_Holocene_Year;

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Holocene_Chk =>
            Display_Holocene_Year (2012);
            Display_Holocene_Year (2020);
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

131.2 List of events

Goal: create a system to manage a list of events.

Steps:

1. Implement the `Events` package.
    1. Declare the `Event_Item` type.
    2. Declare the `Event_Items` type.
2. Implement the `Events.Lists` package.
    1. Declare the `Event_List` type.
    2. Implement the `Add` procedure.
    3. Implement the `Display` procedure.

Requirements:

1. The `Event_Item` type (from the `Events` package) contains the *description of an event*.
    1. This description shall be stored in an access-to-string type.
2. The `Event_Items` type stores a list of events.
    1. This will be used later to represent multiple events for a specific date.
    2. You shall use a vector for this type.
3. The `Events.Lists` package contains the subprograms that are used in the test application.
4. The `Event_List` type (from the `Events.Lists` package) maps a list of events to a specific date.
    1. You must use the `Event_Items` type for the list of events.
    2. You shall use the `Time` type from the `Ada.Calendar` package for the dates.

3. Since we expect the events to be ordered by the date, you shall use ordered maps for the `Event_List` type.

5. Procedure `Add` adds an event into the list of events for a specific date.
6. Procedure `Display` must display all events for each date (ordered by date) using the following format:

```
<event_date #1>
    <description of item #1a>
    <description of item #1b>
<event_date #2>
    <description of item #2a>
    <description of item #2b>
```

1. You should use the auxiliary `Date_Image` function — available in the body of the `Events.Lists` package — to display the date in the `YYYY-MM-DD` format.

Remarks:

1. Let's briefly illustrate the expected output of this system.
    1. Consider the following example:

```
with Ada.Calendar;
with Ada.Calendar.Formatting; use Ada.Calendar.Formatting;

with Events.Lists;            use Events.Lists;

procedure Test is
   EL : Event_List;
begin
   EL.Add (Time_Of (2019, 4, 16),
           "Item #2");
   EL.Add (Time_Of (2019, 4, 15),
           "Item #1");
   EL.Add (Time_Of (2019, 4, 16),
           "Item #3");
   EL.Display;
end Test;
```

    2. The expected output of the `Test` procedure must be:

```
EVENTS LIST
- 2019-04-15
    - Item #1
- 2019-04-16
    - Item #2
    - Item #3
```

Listing 2823: events.ads

```
package Events is

   type Event_Item is null record;

   type Event_Items is null record;

end Events;
```

Listing 2824: events-lists.ads

```
with Ada.Calendar; use Ada.Calendar;

package Events.Lists is

   type Event_List is tagged private;

   procedure Add (Events     : in out Event_List;
                  Event_Time :        Time;
                  Event      :        String);

   procedure Display (Events : Event_List);

private

   type Event_List is tagged null record;

end Events.Lists;
```

Listing 2825: events-lists.adb

18                     "Final check");
19             EL.Add (Time_Of (2018, 2, 16),
20                     "Release");
21             EL.Add (Time_Of (2018, 12, 3),
22                     "Brother's birthday");
23             EL.Add (Time_Of (2018, 1, 1),
24                     "New Year's Day");
25             EL.Display;
26       end case;
27    end Check;
28
29 begin
30    if Argument_Count < 1 then
31       Put_Line ("ERROR: missing arguments! Exiting...");
32       return;
33    elsif Argument_Count > 1 then
34       Put_Line ("Ignoring additional arguments...");
35    end if;
36
37    Check (Test_Case_Index'Value (Argument (1)));
38 end Main;
```

CHAPTER

TWO

STANDARD LIBRARY: STRINGS

132.1 Concatenation

Goal: implement functions to concatenate an array of unbounded strings.

Steps:

1. Implement the `Str_Concat` package.
    1. Implement the `Concat` function for `Unbounded_String`.
    2. Implement the `Concat` function for **`String`**.

Requirements:

1. The first `Concat` function receives an unconstrained array of unbounded strings and returns the concatenation of those strings as an unbounded string.
    1. The second `Concat` function has the same parameters, but returns a standard string (**`String`** type).
2. Both `Concat` functions have the following parameters:
    1. An unconstrained array of `Unbounded_String` strings (`Unbounded_Strings` type).
    2. `Trim_Str`, a Boolean parameter indicating whether each unbounded string must be trimmed.
    3. `Add_Whitespace`, a Boolean parameter indicating whether a whitespace shall be added between each unbounded string and the next one.
        1. No whitespace shall be added after the last string of the array.

Remarks:

1. You can use the `Trim` function from the `Ada.Strings.Unbounded` package.

Listing 2827: str_concat.ads

```
with Ada.Strings.Unbounded; use Ada.Strings.Unbounded;

package Str_Concat is

   type Unbounded_Strings is array (Positive range <>) of Unbounded_String;

   function Concat (USA             : Unbounded_Strings;
                    Trim_Str        : Boolean;
                    Add_Whitespace : Boolean) return Unbounded_String;

   function Concat (USA             : Unbounded_Strings;
                    Trim_Str        : Boolean;
                    Add_Whitespace : Boolean) return String;

end Str_Concat;
```

Listing 2828: str_concat.adb

```
with Ada.Strings; use Ada.Strings;

package body Str_Concat is

   function Concat (USA            : Unbounded_Strings;
                    Trim_Str       : Boolean;
                    Add_Whitespace : Boolean) return Unbounded_String is
   begin
      return "";
   end Concat;

   function Concat (USA            : Unbounded_Strings;
                    Trim_Str       : Boolean;
                    Add_Whitespace : Boolean) return String is
   begin
      return "";
   end Concat;

end Str_Concat;
```

Listing 2829: main.adb

```
with Ada.Command_Line;        use Ada.Command_Line;
with Ada.Text_IO;             use Ada.Text_IO;
with Ada.Strings.Unbounded;   use Ada.Strings.Unbounded;

with Str_Concat;              use Str_Concat;

procedure Main is
   type Test_Case_Index is
     (Unbounded_Concat_No_Trim_No_WS_Chk,
      Unbounded_Concat_Trim_No_WS_Chk,
      String_Concat_Trim_WS_Chk,
      Concat_Single_Element);

   procedure Check (TC : Test_Case_Index) is
   begin
      case TC is
         when Unbounded_Concat_No_Trim_No_WS_Chk =>
            declare
               S : constant Unbounded_Strings := (
                  To_Unbounded_String ("Hello"),
                  To_Unbounded_String (" World"),
                  To_Unbounded_String ("!"));
            begin
               Put_Line (To_String (Concat (S, False, False)));
            end;
         when Unbounded_Concat_Trim_No_WS_Chk =>
            declare
               S : constant Unbounded_Strings := (
                  To_Unbounded_String (" This "),
                  To_Unbounded_String (" _is_ "),
                  To_Unbounded_String ("  a   "),
                  To_Unbounded_String (" _check "));
            begin
               Put_Line (To_String (Concat (S, True, False)));
            end;
         when String_Concat_Trim_WS_Chk =>
            declare
```

(continues on next page)

(continued from previous page)

```
               S : constant Unbounded_Strings := (
                   To_Unbounded_String ("  This  "),
                   To_Unbounded_String ("  is a  "),
                   To_Unbounded_String ("  test.  "));
            begin
               Put_Line (Concat (S, True, True));
            end;
         when Concat_Single_Element =>
            declare
               S : constant Unbounded_Strings := (
                   1 => To_Unbounded_String ("  Hi "));
            begin
               Put_Line (Concat (S, True, True));
            end;
      end case;
   end Check;

begin
   if Argument_Count < 1 then
      Put_Line ("ERROR: missing arguments! Exiting...");
      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

132.2 List of events

Goal: create a system to manage a list of events.

Steps:

1. Implement the `Events` package.
    1. Declare the `Event_Item` subtype.
2. Implement the `Events.Lists` package.
    1. Adapt the `Add` procedure.
    2. Adapt the `Display` procedure.

Requirements:

1. The `Event_Item` type (from the `Events` package) contains the *description of an event*.
    1. This description is declared as a subtype of unbounded string.
2. Procedure `Add` adds an event into the list of events for a specific date.
    1. The declaration of `E` needs to be adapted to use unbounded strings.
3. Procedure `Display` must display all events for each date (ordered by date) using the following format:
    1. The arguments to `Put_Line` need to be adapted to use unbounded strings.

Remarks:

1. We use the lab on the list of events from the previous chapter (*Standard library: Dates & Times* (page 2439)) as a starting point.

Listing 2830: events.ads

```
with Ada.Containers.Vectors;

package Events is

   --  subtype Event_Item is

   package Event_Item_Containers is new
     Ada.Containers.Vectors
       (Index_Type   => Positive,
        Element_Type => Event_Item);

   subtype Event_Items is Event_Item_Containers.Vector;

end Events;
```

Listing 2831: events-lists.ads

```
with Ada.Calendar;                use Ada.Calendar;
with Ada.Containers.Ordered_Maps;

package Events.Lists is

   type Event_List is tagged private;

   procedure Add (Events     : in out Event_List;
                  Event_Time :        Time;
                  Event      :        String);

   procedure Display (Events : Event_List);

private

   package Event_Time_Item_Containers is new
     Ada.Containers.Ordered_Maps
       (Key_Type         => Time,
        Element_Type     => Event_Items,
        "="              => Event_Item_Containers."=");

   type Event_List is new Event_Time_Item_Containers.Map with null record;

end Events.Lists;
```

Listing 2832: events-lists.adb

```
with Ada.Text_IO;             use Ada.Text_IO;
with Ada.Calendar.Formatting; use Ada.Calendar.Formatting;

package body Events.Lists is

   procedure Add (Events     : in out Event_List;
                  Event_Time : Time;
                  Event      : String) is
      use Event_Item_Containers;
      E : constant Event_Item := new String'(Event);
   begin
      if not Events.Contains (Event_Time) then
         Events.Include (Event_Time, Empty_Vector);
      end if;
      Events (Event_Time).Append (E);
```

(continues on next page)

(continued from previous page)

```
   end Add;

   function Date_Image (T : Time) return String is
      Date_Img : constant String := Image (T);
   begin
      return Date_Img (1 .. 10);
   end;

   procedure Display (Events : Event_List) is
      use Event_Time_Item_Containers;
      T : Time;
   begin
      Put_Line ("EVENTS LIST");
      for C in Events.Iterate loop

41       return;
42    elsif Argument_Count > 1 then
43       Put_Line ("Ignoring additional arguments...");
44    end if;
45
46    Check (Test_Case_Index'Value (Argument (1)));
47 end Main;
```

CHAPTER

THREE

STANDARD LIBRARY: NUMERICS

133.1 Decibel Factor

Goal: implement functions to convert from Decibel values to factors and vice-versa.

Steps:

1. Implement the `Decibels` package.
    1. Implement the `To_Decibel` function.
    2. Implement the `To_Factor` function.

Requirements:

1. The subtypes `Decibel` and `Factor` are based on a floating-point type.
2. Function `To_Decibel` converts a multiplication factor (or ratio) to decibels.
    - For the implementation, use $20 * log_{10}(F)$, where *F* is the factor/ratio.
3. Function `To_Factor` converts a value in decibels to a multiplication factor (or ratio).
    - For the implementation, use $10^{D/20}$, where *D* is the value in Decibel.

Remarks:

1. The Decibel[605] is used to express the ratio of two values on a logarithmic scale.
    1. For example, an increase of 6 dB corresponds roughly to a multiplication by two (or an increase by 100 % of the original value).
2. You can find the functions that you'll need for the calculation in the `Ada.Numerics.Elementary_Functions` package.

Listing 2834: decibels.ads

```
package Decibels is

   subtype Decibel is Float;
   subtype Factor  is Float;

   function To_Decibel (F : Factor) return Decibel;

   function To_Factor (D : Decibel) return Factor;

end Decibels;
```

[605] https://en.wikipedia.org/wiki/Decibel

Listing 2835: decibels.adb

```
package body Decibels is

   function To_Decibel (F : Factor) return Decibel is
   begin
      return 0.0;
   end To_Decibel;

133.2 Root-Mean-Square

Goal: implement a function to calculate the root-mean-square of a sequence of values.

Steps:

1. Implement the `Signals` package.
    1. Implement the `Rms` function.

Requirements:

1. Subtype `Sig_Value` is based on a floating-point type.
2. Type `Signal` is an unconstrained array of `Sig_Value` elements.
3. Function `Rms` calculates the RMS of a sequence of values stored in an array of type `Signal`.
    1. See the remarks below for a description of the RMS calculation.

Remarks:

1. The root-mean-square[606] (RMS) value is important information associated with sequences of values.
    1. It's used, for example, as a measurement for signal processing.
    2. It is calculated by:
        1. Creating a sequence S with the square of each value of an input sequence S_{in}.
        2. Calculating the mean value M of the sequence S.
        3. Calculating the square-root R of M.
    3. You can optimize the algorithm above by combining steps #1 and #2 into a single step.

Listing 2837: signals.ads

```
package Signals is

   subtype Sig_Value is Float;

   type Signal is array (Natural range <>) of Sig_Value;

   function Rms (S : Signal) return Sig_Value;

end Signals;

      return;
   elsif Argument_Count > 1 then
      Put_Line ("Ignoring additional arguments...");
   end if;

   Check (Test_Case_Index'Value (Argument (1)));
end Main;
```

133.3 Rotation

Goal: use complex numbers to calculate the positions of an object in a circle after rotation.

Steps:

1. Implement the `Rotation` package.
    1. Implement the `Rotation` function.

Requirements:

1. Type `Complex_Points` is an unconstrained array of complex values.
2. Function `Rotation` returns a list of positions (represented by the `Complex_Points` type) when dividing a circle in `N` equal slices.
    1. See the remarks below for a more detailed explanation.
    2. You must use functions from `Ada.Numerics.Complex_Types` to implement `Rotation`.
3. Subtype `Angle` is based on a floating-point type.
4. Type `Angles` is an unconstrained array of angles.
5. Function `To_Angles` returns a list of angles based on an input list of positions.

Remarks:

1. Complex numbers are particularly useful in computer graphics to simplify the calculation of rotations.
    1. For example, let's assume you've drawn an object on your screen on position (1.0, 0.0).
    2. Now, you want to move this object in a circular path — i.e. make it rotate around position (0.0, 0.0) on your screen.
        - You could use *sine* and *cosine* functions to calculate each position of the path.
        - However, you could also calculate the positions using complex numbers.
2. In this exercise, you'll use complex numbers to calculate the positions of an object that starts on zero degrees — on position (1.0, 0.0) — and rotates around (0.0, 0.0) for *N* slices of a circle.
    1. For example, if we divide the circle in four slices, the object's path will consist of following points / positions:

        ```
        Point #1: ( 1.0,  0.0)
        Point #2: ( 0.0,  1.0)
        Point #3: (-1.0,  0.0)
        Point #4: ( 0.0, -1.0)
        Point #5: ( 1.0,  0.0)
        ```

        1. As expected, point #5 is equal to the starting point (point #1), since the object rotates around (0.0, 0.0) and returns to the starting point.
    2. We can also describe this path in terms of angles. The following list presents the angles for the path on a four-sliced circle:

        ```
        Point #1:    0.00 degrees
        Point #2:   90.00 degrees
        Point #3:  180.00 degrees
        Point #4:  -90.00 degrees (= 270 degrees)
        Point #5:    0.00 degrees
        ```

        1. To rotate a complex number simply multiply it by a unit vector whose arg is the radian angle to be rotated: $Z = e^{\frac{2\pi}{N}}$

Listing 2842: rotation.ads

Workshop project: Learn to write maintainable bug-free code with SPARK Ada.

This document was written by Robert Tice.

Note

The code examples in this course use an 80-column limit, which is a typical limit for Ada code. Note that, on devices with a small screen size, some code examples might be difficult to read.

CHAPTER

FIVE

LET'S BUILD A STACK

In this lab we will build a stack data structure and use the SPARK provers to find the errors in the below implementation.

135.1 Background

So, what is a stack?

A stack is like a pile of dishes...

1. The pile starts out empty.
2. You add (`push`) a new plate (`data`) to the stack by placing it on the top of the pile.
3. To get plates (`data`) out, you take the one off the top of the pile (`pop`).
4. Our stack has a maximum height (`size`) of 9 dishes

Pushing items onto the stack

Here's what should happen if we pushed the string `MLH` onto the stack.

Step 0:
Empty

1:	
2:	
3:	
4:	
5:	

Last = 0

Step 1:
Push("M")

1:	M
2:	
3:	
4:	
5:	

Last = 1

Step 2:
Push("L")

1:	M
2:	L
3:	
4:	
5:	

Last = 2

Step 3:
Push("H")

1:	M
2:	L
3:	H
4:	
5:	

Last = 3

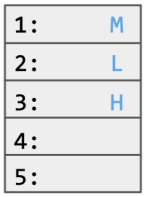
Step 4:
Top()

1:	M
2:	L
3:	H
4:	
5:	

Last = 3
returns:
'H'

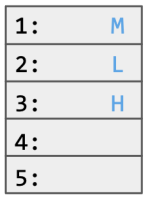
The list starts out empty. Each time we push a character onto the stack, `Last` increments by 1.

Popping items from the stack



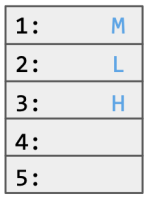
Here's what should happen if we popped 2 characters off our stack & then cleared it.

Step 0:
Start



Last = 3

Step 1:
Pop()



Last = 2
returns:
'H'

Step 2:
Pop()

Last = 1
returns:
'L'

Step 3:
Clear()

Last = 0

Note that pop and `clear` don't unset the `Storage` array's elements, they just change the value of `Last`.

135.2 Input Format

N inputs will be read from stdin/console as inputs, C to the stack.

135.3 Constraints

1 <= N <= 1000

C is any character. Characters d and p will be special characters corresponding to the below commands:

p => Pops a character off the stack

d => Prints the current characters in the stack

135.4 Output Format

If the stack currently has the characters "M", "L", and "H" then the program should print the stack like this:

[M, L, H]

135.5 Sample Input

M L H d p d p d p d

135.6 Sample Output

[M, L, H] [M, L] [M] []

About the Authors

Frédéric Pothon

During his professional career dating back to the 1980s, Frédéric Pothon has been a recognized expert in the area of software aspects of certification (most notably DO - 178/ED - 12, Levels A, B, and C). He was a member of the EUROCAE/RTCA group that produced DO - 248B/ED - 94B, which provides supporting information for the DO - 178B/ED - 12B standard. Mr. Pothon has led projects at Turboméca (now Safran Helicopter Engines) and Airbus, where he was responsible for software methodologies and quality engineering processes. He founded the company ACG-Solutions in 2007 and worked as an independent consulting engineer, providing training, audits, and support, and he was involved in several research projects. Mr. Pothon is an expert in the qualification and utilization of automatic code generation tools for model-based development, and he served as co-chair of the Tool Qualification subgroup during the DO - 178C/ED - 12C project.

Quentin Ochem

Quentin Ochem is the Chief Product and Revenue Officer at AdaCore, where he oversees marketing, sales, and product management while steering the company's strategic initiatives. He joined AdaCore in 2005 to work on the company's Integrated Development Environments and cross-language bindings. With an extensive background in software engineering in high-integrity domains such as avionics and defense, he has served leading roles in technical sales, customer training, and product development. Notably, he has conducted training on the Ada language, AdaCore tools, and the DO - 178B/ED - 12B and DO - 178C/ED - 12C software certification standards. In 2021 he stepped into his current role, directing the company's strategic initiatives.

Foreword

The guidance in the DO - 178C/ED - 12C standard and its associated technology-specific supplements helps achieve confidence that airborne software meets its requirements. Certifying that a system complies with this guidance is a challenging task, especially for the verification activities, but appropriate usage of qualified tools and specialized run-time libraries can significantly simplify the effort. This document explains how a number of technologies offered by AdaCore — tools, libraries, and supplemental services — can help. It covers not only the "core" DO - 178C/ED - 12C standard but also the technology supplements: Object-Oriented Technology and Related Techniques DO - 332/ED - 217, and Formal Methods (DO - 333/ED - 216). The content is based on the authors' many years of practical experience with the certification of airborne software, with the Ada and SPARK programming languages, and with the technologies addressed by the DO - 178C/ED - 12C supplements.

We gratefully acknowledge the assistance of Ben Brosgol (AdaCore) for his review of and contributions to the material presented in this document.

March 2017

Foreword to V2.1

This revised booklet reflects the evolution of and enhancements to AdaCore's products since the earlier edition. Among other updates, the static analysis tools supplementing the GNAT Pro development environment have been integrated into a cohesive toolset (*CodeSonar for Ada*). The dynamic analysis tools have likewise been consolidated, and the resulting *GNAT Dynamic Analysis Suite* has introduced a fuzzing tool — *GNATfuzz* — which exercises the software with invalid input and checks for failsafe behavior.

I would like to express my appreciation to Olivier Appere (AdaCore) for his detailed and helpful review of the content for the revised booklet.

Ben Brosgol, AdaCore

CHAPTER

SIX

INTRODUCTION

This document explains how to use AdaCore's technologies — the company's tools, run-time libraries, and associated services — in conjunction with the safety-related standards for airborne software: DO - 178C/ED - 12C and its technology supplements and tool qualification considerations. It describes how AdaCore's technologies fit into a project's software life cycle processes, and how they can satisfy various objectives of the standards. Many of the advantages of AdaCore's products stem from the software engineering support found in the Ada programming language, including features (such as contract-based programming) introduced in Ada 2012[610]. Other advantages draw directly from the formally analyzable SPARK subset of Ada[611],[612],[613]. As a result, this document identifies how Ada and SPARK contribute toward the development of reliable software. AdaCore personnel have played key roles in the design and implementation of both of these languages.

Although DO - 178C/ED - 12C doesn't prescribe any specific software life cycle, the development and verification processes that it encompasses can be represented as a variation of the traditional "V-model"[609]. As shown in Fig. 1, AdaCore's products and the Ada and SPARK languages contribute principally to the bottom portions of the *V* — coding and integration and their verification. The Table annotations in Fig. 1 refer to the tables in DO - 178C/ED - 12C and, when applicable, specific objectives in those tables.

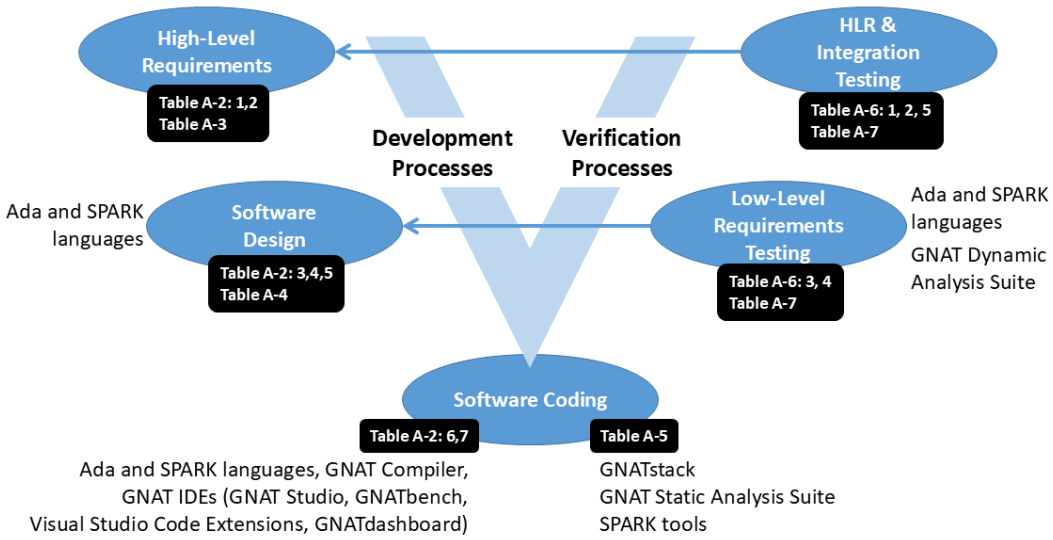

Fig. 1: AdaCore Technologies and DO - 178C/ED - 12C Life Cycle Processes

Complementing AdaCore's support for Ada and SPARK, the company offers tools and technologies for C, C++ and Rust. Although C lacks the built-in checks as well as other functionality that Ada provides, AdaCore's Ada and C toolchains have similar capabilities. And mixed-language applications can take advantage of Ada's interface checking that is performed during inter-module communication.

AdaCore's Ada and C compilers can help developers produce reliable software, targeting embedded platforms with RTOSes as well as *bare metal* configurations. These are available with long term support, certifiable run-time libraries, and source-to-object traceability analyses as required for DO - 178C/ED - 12C Level A. Supplementing the compilers are a comprehensive set of static and dynamic analysis tools, including a code standard enforcer, a vulnerability and logic error detector, test and coverage analyzers, and a fuzzing tool.

A number of these tools are qualifiable with respect to the DO - 330/ED - 215 standard (Tool Qualification Considerations). The use of qualified tools can save considerable effort during development and/or verification since the output of the tools does not need to be manually checked. Qualification material, at the applicable Tool Qualification Level (TQL), is available for specific AdaCore tools.

Supplementing the core DO - 178C/ED - 12C standard are three supplements that address specific technologies:

- *DO-331/ED-218: Model-Based Development and Verification*

  AdaCore's tools and technologies can be used in conjunction with model-based methods but do not relate directly to the issues addressed in DO - 331/ED - 218.

- *DO-332/ED-217: Object-Oriented Technology and Related Techniques*

  The Ada and SPARK languages provide specific features that help meet the objectives of DO - 332/ED - 217, thus allowing developers to exploit Object Orientation (e.g., class hierarchies and inheritance for specifying data relationships) in a certified application.

- *DO-333/ED-216: Formal Methods*

  The SPARK language and toolset directly support DO - 333/ED - 216, allowing the use of formal proofs to replace some low-level testing.

The technologies and associated options presented in this document are known to be acceptable, and certification authorities have already accepted most of them on actual projects. However, acceptance is project dependent. An activity using a technique or method may be considered as appropriate to satisfy one or several DO - 178C/ED - 12C objectives for one project (determined by the development standards, the input complexity, the target computer and system environment) but not necessarily on another project. The effort and amount of justification to gain approval may also differ from one auditor to another, depending on their background. Whenever a new tool, method, or technique is introduced, it's important to open a discussion with AdaCore and the designated authority to confirm its acceptability. The level of detail in the process description provided in the project plans and standard is a key factor in gaining acceptance.

CHAPTER

SEVEN

THE DO-178C/ED-12C STANDARDS SUITE

137.1 Overview

"Every State has complete and exclusive sovereignty over the airspace above its territory." This general principle was codified in Article 1 of the Convention on International Civil Aviation (the "Chicago Convention") in 1944[614]. To control the airspace, harmonized regulations have been formulated to ensure that the aircraft are airworthy.

A type certificate is issued by a certification authority to signify the airworthiness of an aircraft manufacturing design. The certificate reflects a determination made by the regulating body that the aircraft is manufactured according to an approved design, and that the design complies with airworthiness requirements. To meet those requirements the aircraft and each subassembly must also be approved. Typically, requirements established by a regulating body refer to "Minimum Operating Performance Standards" (MOPS) and a set of recognized "Acceptable Means of Compliance" such as DO - 178/ED - 12 for software, DO - 160/ED - 14 for environmental conditions and test procedures, and DO - 254/ED - 80 for Complex Electronic Hardware.

DO-178C/ED-12C - Software Considerations in Airborne Systems and Equipment Certification[615] — was issued in December 2011, developed jointly by RTCA, Inc., and EUROCAE. It is the primary document by which certification authorities such as the FAA, EASA, and Transport Canada approve all commercial software-based aerospace systems.

The DO - 178C/ED - 12C document suite comprises:

- The core document, which is a revision of the previous release (DO - 178B/ED - 12B). The changes are mostly clarifications, and also address the use of "Parameter Data Items" (e.g., Configuration tables)
- DO - 278A/ED - 109A, which is similar to DO - 178C/ED - 12C and addresses ground-based software used in the domain of CNS/ATM (Communication Navigation Surveillance/Air Traffic Management)
- DO - 248C/ED - 94C (Supporting Information for DO - 178C/ED - 12C and DO - 278A/ED - 109A), which explains the rationale behind the guidance provided in the core documents
- Three technology-specific supplements
  - DO - 331/ED - 218: Model-Based Development and Verification
  - DO - 332/ED - 217: Object Oriented Technology and Related Techniques
  - DO - 333/ED - 216: Formal Methods

[614] ICAO. *Convention on International Civil Aviation*. ICAO, 1944. URL: https://www.icao.int/publications/documents/7300_orig.pdf.
[615] RCTA. *Software Considerations in Airborne Systems and Equipment Certification*. RCTA, 2011. URL: https://my.rtca.org/productdetails?id=a1B36000001IcmqEAC.

Each supplement adapts the core document guidance as appropriate for its respective technology. These supplements are not standalone documents but must be used in conjunction with DO - 178C/ED - 12C or DO - 278A/ED - 109A.

- DO - 330/ED - 215 (Software Tool Qualification Considerations), providing guidance for qualifying software tools. This standard is not specific to DO - 178C/ED - 12C and may be applied to software certification in other application domains.

Details on how to use these standards in practice may be found in[616].

One of the main principles of the DO - 178C/ED - 12C document suite is to be "objective oriented". The guidance in each document consists of a set of objectives that relate to the various software life-cycle processes (planning, development, verification, configuration management, quality assurance, certification liaison). The objectives that must be met for a particular software component depend on the software level (also known as a *Design Assurance Level* or *DAL*) of the component. The level in turn is based on the potential effect of an anomaly in that software component on the continued safe operation of the aircraft. Software levels range from *E* (the lowest) where there is no effect, to *A* (the highest) where an anomaly can cause the loss of the aircraft. A software component's level is established as part of the system life-cycle processes.

To gain software approval for a system, the applicant has to demonstrate that the objectives relevant to the software level for each component have been met. To achieve this goal, the development team specifies the various software life-cycle activities (based on those recommended by DO - 178C/ED - 12C and/or others), and its associated methods, environment, and organization/management. In case the chosen methods are addressed by one of the technology supplements, additional or alternative objectives must also be satisfied. The technology supplements may replace or add objectives and/or activities.

137.2 Software Tool Qualification Considerations: DO-330/ED-215

A software tool needs to be qualified when a process is automated, eliminated, or reduced, but its outputs are not verified. The systematic verification of the tool outputs is replaced by activities performed on the tool itself: the *tool qualification*. The qualification effort depends on the assurance level of the airborne software and the possible effect that an error in the tool may have on this software. The resulting combination, the Tool Qualification Level, is a 5 level scale, from TQL-5 (the lowest level, applicable to software tools that cannot insert an error in the resulting software, but might fail to detect an error) to TQL-1 (the highest, applicable to software tools that can insert an error in software at level A).

A tool is only qualified in the context of a specific project, for a specific certification credit, expressed in terms of objectives and activities. Achieving qualification for a tool on a specific project does of course greatly increase the likelihood of being able to qualify the tool on another project. However, a different project may have different processes or requirements, or develop software with different environment constraints. As a result, the qualifiability of a tool needs to be systematically assessed on a case-by-case basis.

Although many references are made in the literature about *qualified* tools, strictly speaking this term should only be used in the context of a specific project. Tools provided by tool vendors, independently of any project, should be identified as *qualifiable* only. The tool qualification document guidance DO - 330/ED - 215 includes specific objectives that can only be satisfied in the context of a given project environment.

Throughout this document, the applicable tool qualification level is identified together with the relevant objective or activity for which credit may be sought. The qualification activities have been performed with respect to DO - 330/ED - 215 at the applicable Tool Qualification

[616] Leanna Rierson. *Developing Safety-Critical Software: A Practical Guide for Aviation Software and DO-178C Compliance*. CRC Press, 2013.

Level. Tool qualification material is available to customers as a supplement to AdaCore's GNAT Pro Assurance product.

137.3 Model-Based Development and Verification Supplement: DO-331/ED-218

Model-based development covers a wide range of techniques for representing the software requirements and/or architecture, most often through a graphical notation. The source code itself is not considered as a model. Well known examples include UML for software architecture, SysSML for system representation, and Simulink© for control algorithms and related requirements. DO - 331/ED - 218 presents the objectives and activities associated with the use of such techniques.

The main added value of the supplement is its guidance on how to use model simulation and obtain certification credit. AdaCore's tools and technologies can be used in conjunction with model-based methods but do not relate directly to the issues addressed in this supplement.

137.4 Object-Oriented Technology and Related Techniques Supplement: DO-332/ED-217

Although DO - 332/ED - 217 is often referred to as the "object oriented supplement", the "related techniques" mentioned in the title are equally relevant and are addressed in detail. They may be used in conjunction with Object-Oriented Technology (OOT) but are not necessarily related to OO features. Such *related techniques* include virtualization, genericity (also known as templates), exceptions, overloading, and dynamic memory management.

Considering the breadth of features covered by DO - 332/ED - 217, at least some of its guidance should be followed regardless of whether the actual application is using object orientation. For example, type conversion is probably present in most code bases regardless of which language is being used.

The DO - 332/ED - 217 supplement is much more code-centric than the others, and only two objectives are added: one related to local type consistency (dynamic dispatching) and another one related to dynamic memory. All other guidance takes the form of additional activities for existing DO - 178C/ED - 12C objectives.

Of particular relevance is the supplement's *Vulnerability Analysis* annex. Although not binding, it explains in detail what is behind these additional activities. The following features in particular may need to be addressed when Ada is used:

- Inheritance / local type consistency
- Parametric polymorphism (genericity)
- Overloading
- Type conversion
- Exception management
- Dynamic memory
- Component-based development

The Ada language, the precautions taken during the design and coding processes, and the use of AdaCore tools combine to help address or mitigate the vulnerabilities associated with these features.

137.5 Formal Methods Supplement: DO-333/ED-216

DO - 333/ED - 216 provides guidance on the use of formal methods. A formal method is defined as "a formal model combined with a formal analysis". A formal model should be precise, unambiguous and have a mathematically defined syntax and semantics. The formal analysis should be sound; i.e., if it is supposed to determine whether the formal model (for example the software source code in a language such as SPARK) satisfies a given property, then the analysis should never assert that the property holds when in fact it does not.

A formal method may be used to satisfy DO - 178C/ED - 12C verification objectives; formal analysis may therefore replace some reviews, analyses and tests. Almost all verification objectives are potential candidates for formal methods.

In DO - 178C/ED - 12C, the purpose of testing is to verify the Executable Object Code (EOC) based on the requirements. The main innovation of DO-333 / ED-216 is to allow the use of formal methods to replace some categories of tests. In fact, with the exception of software / hardware integration tests showing that the EOC is compatible with the target computer, the other objectives of EOC verification may be satisfied by formal analysis. This is a significant added value. However, employing formal analysis to replace tests is a new concept in the avionics domain, with somewhat limited experience in practice thus far (see[617] for further information). As noted in[618], a significant issue is how to demonstrate that the compiler generates code that properly preserves the properties that have been formally demonstrated for the source code. Running the integration tests both with and without the contracts being executed, and showing that the results are the same in both cases, is one way to gain the necessary confidence that properties have been preserved in the EOC.

Details from tool providers on the underlying models or mathematical theories implemented in the tool are necessary to assess the maturity of the method. Then substantiation and justification need to be documented, typically in the Plan for Software Aspects of Certification (PSAC), and provided to certification authorities at an early stage for review.

AdaCore provides the SPARK technology as a formal method that can eliminate or reduce the testing based on low-level requirements. Using SPARK will also get full or partial credit for other objectives, such as requirements and code accuracy and consistency, verifiability, etc. Its usage is consistent with the example provided in Appendix B of DO - 333/ED - 216, "FM.B.1.5.1 Unit Proof", and a SPARK version of this example is shown in *SPARK Development Cycle Example* (page 2646). Certification credit for using formal proofs is summarized in Fig. 2:

CHAPTER

EIGHT

ADACORE TOOLS AND TECHNOLOGIES OVERVIEW

138.1 Ada

138.1.1 Background

Ada is a modern programming language designed for large, long-lived applications — and embedded systems in particular — where reliability, maintainability, and efficiency are essential. It was originally developed in the early 1980s (this version is generally known as Ada 83) by a team led by Jean Ichbiah at CII-Honeywell-Bull in France. The language was revised and enhanced in an upward compatible fashion in the early 1990s, under the leadership of Tucker Taft from Intermetrics in the U.S. The resulting language, Ada 95, was the first internationally standardized (ISO) object-oriented language. Under the auspices of ISO, a further (minor) revision was completed as an amendment to the standard; this version of the language is known as Ada 2005. Additional features (including support for contract-based programming in the form of subprogram pre- and postconditions and type invariants) were added in the Ada 2012 version of the language standard, and a number of features to increase the language's expressiveness were introduced in Ada 2022 (see[620],[621],[622],[623] for information about Ada).

The name *Ada* is not an acronym; it was chosen in honor of Augusta Ada Lovelace (1815-1852), a mathematician who is regarded as the world's first programmer because of her work with Charles Babbage. She was also the daughter of the poet Lord Byron.

Ada is seeing significant usage worldwide in high-integrity / safety-critical / high-security domains including commercial and military aircraft avionics, air traffic control, railroad systems, and medical devices. With its embodiment of modern software engineering principles, Ada is an excellent teaching language for both introductory and advanced computer science courses, and it has been the subject of significant university research especially in the area of real-time technologies. The so-called Ravenscar profile — a subset of the language's concurrency features with deterministic semantics — broke new ground in supporting the use of concurrent programming in high assurance software.

AdaCore has a long history and close connection with the Ada programming language. Company members worked on the original Ada 83 design and review and played key roles in the Ada 95 project as well as the subsequent revisions. AdaCore's initial GNAT compiler was essential to the growth of Ada 95; it was delivered at the time of the language's standardization, thus guaranteeing that users would have a quality implementation for transitioning to Ada 95 from Ada 83 or other languages.

[623] ISO/IEC. *Ada Language Reference Manual, Language and Standard Libraries*. AdaIC, 2022. URL: https://www.adaic.org/ada-resources/standards/ada22/.

138.1.2 Language Overview

Ada is multi-faceted. From one perspective it is a classical stack-based general-purpose language, not tied to any specific development methodology. It has a simple syntax, structured control statements, flexible data composition facilities, strong type checking, traditional features for code modularization (*subprograms*), and a mechanism for detecting and responding to exceptional run-time conditions (*exception handling*). But it also includes much more:

Scalar ranges

Unlike languages based on C syntax (such as C++, Java, and C#), Ada allows the programmer to simply and explicitly specify the range of values that are permitted for variables of scalar types (integer, floating-point, fixed-point, and enumeration types). The attempted assignment of an out-of-range value causes a run-time error. The ability to specify range constraints makes programmer intent explicit and makes it easier to detect a major source of coding and user input errors. It also provides useful information to static analysis tools and facilitates automated proofs of program properties.

Here's an example of an integer scalar range:

```
declare
   Score : Integer range 1..100;
   N     : Integer;
begin
   ... -- Code that assigns a value to N
   Score := N;
   -- A run-time check verifies that N is within the range 1..100
   -- If this check fails, the Constraint_Error exception is raised
end;
```

Contract-based programming

A feature introduced in Ada 2012 allows extending a subprogram specification or a type/subtype declaration with a contract (a Boolean assertion). Subprogram contracts take the form of preconditions and postconditions, type contracts are used for invariants, and subtype contracts provide generalized constraints (predicates). Through contracts the developer can formalize the intended behavior of the application, and can verify this behavior by testing, static analysis or formal proof.

Here's a skeletal example that illustrates contract-based programming; a `Table` object is a fixed-length container for distinct **`Float`** values.

```
package Table_Pkg is
   type Table is private;  -- Encapsulated type

   procedure Insert (T : in out Table; Item: in Float)
     with Pre  => not Is_Full(T) and not Contains(T, Item),
          Post => Contains(T, Item);

   procedure Remove (T : in out Table; Item: out Float);
     with Pre  => Contains(T, Item),
          Post => not Contains(T, Item);

   function Is_Full  (T : in Table) return Boolean;
   function Contains (T : in Table; Item: in Float)
      return Boolean;
   ...
private
   ...
end Table_Pkg;
```

A compiler option controls whether the pre- and postconditions are checked at run time. If checks are enabled, any pre- or postcondition failure — i.e., the contract's Boolean expression evaluating to `False` — raises the `Assertion_Error` exception.

Programming in the large

The original Ada 83 design introduced the package construct, a feature that supports encapsulation (*information hiding*) and modularization, and which allows the developer to control the namespace that is accessible within a given compilation unit. Ada 95 introduced the concept of *child units*, adding considerable flexibility and easing the design of very large systems. Ada 2005 extended the language's modularization facilities by allowing mutual references between package specifications, thus making it easier to interface with languages such as Java.

Generic templates

A key to reusable components is a mechanism for parameterizing modules with respect to data types and other program entities, for example a stack package for an arbitrary element type. Ada meets this requirement through a facility known as *generics*; since the parameterization is done at compile time, run-time performance is not penalized.

Object-Oriented Programming (OOP)

Ada 83 was object-based, allowing the partitioning of a system into modules corresponding to abstract data types or abstract objects. Full OOP support was not provided since, first, it seemed not to be required in the real-time domain that was Ada's primary target, and, second, the apparent need for automatic garbage collection in an OO language would have interfered with predictable and efficient performance.

However, large real-time systems often have components such as GUIs that do not have real-time constraints and that could be most effectively developed using OOP features. In part for this reason, Ada 95 supplies comprehensive support for OOP, through its *tagged type* facility: classes, polymorphism, inheritance, and dynamic binding. Ada 95 does not require automatic garbage collection but rather supplies definitional features allowing the developer to supply type-specific storage reclamation operations (*finalization*). Ada 2005 brought additional OOP features including Java-like interfaces and traditional *obj.op(...)* operation invocation notation.

Ada is methodologically neutral and does not impose a distributed overhead for OOP. If an application does not need OOP, then the OOP features do not have to be used, and there is no run-time penalty. SeePage 2587, 622 or[624] for more details.

Concurrent programming

Ada supplies a structured, high-level facility for concurrency. The unit of concurrency is a program entity known as a *task*. Tasks can communicate implicitly via shared data or explicitly via a synchronous control mechanism known as the rendezvous. A shared data item can be defined abstractly as a *protected object* (a feature introduced in Ada 95), with operations executed under mutual exclusion when invoked from multiple tasks. Asynchronous task interactions are also supported for timeouts, software event notifications, and task termination. Such asynchronous behavior is deferred during certain operations, to prevent the possibility of leaving shared data in an inconsistent state. Mechanisms designed to help take advantage of multi-core architectures were introduced in Ada 2012.

[624] AdaCore. *High-Integrity Object-Oriented Programming in Ada*. AdaCore, 2016. URL: https://www.adacore.com/knowledge/technical-papers/high-integrity-oop-in-ada/.

Systems programming

Both in the *core* language and the Systems Programming Annex, Ada supplies the necessary features for hardware-specific processing. For example, the programmer can specify the bit layout for fields in a record, define alignment and size properties, place data at specific machine addresses, and express specialized code sequences in assembly language. Interrupt handlers can be written in Ada, using the protected type facility.

Real-time programming

Ada's tasking facility and the Real-Time Systems Annex support common idioms such as periodic or event-driven tasks, with features that can help avoid unbounded priority inversions. A protected object locking policy is defined that uses priority ceilings; this has an especially efficient implementation in Ada (mutexes are not required) since protected operations are not allowed to block. Ada 95 defined a task dispatching policy that basically requires tasks to run until blocked or preempted. Subsequent versions of the language standard introduced several other policies, such as Earliest Deadline First.

High-integrity systems

With its emphasis on sound software engineering principles, Ada supports the development of high-integrity applications, including those that need to be certified against safety standards such DO - 178C/ED - 12C for avionics, CENELEC EN 50716:2023 for rail systems, and security standards such as the Common Criteria[625]. Key to Ada's support for high-assurance software is the language's memory safety; this is illustrated by a number of features, including:

- Strong typing

  Data intended for one purpose will not be accessed via inappropriate operations; errors such as treating pointers as integers (or vice versa) are prevented.

- Array bounds checking

  A run-time check guarantees that an array index is within the bounds of the array. This prevents buffer overflow vulnerabilities that are common in C and C++. In many cases a compiler optimization can detect statically that the index is within bounds and thus eliminate any run-time code for the check.

- Prevention of null pointer dereferences

  As with array bounds, pointer dereferences are checked to make sure that the pointer is not null. Again, such checks can often be optimized out.

- Prevention of dangling references

  A scope accessibility check ensures that a pointer cannot reference an object on the stack after exit/return from the scope (block or subprogram) in which the object is declared. Such checks are generally static, with no run-time overhead.

However, the full language may be inappropriate in a safety-critical application, since the generality and flexibility could interfere with traceability / certification requirements. Ada addresses this issue by supplying a compiler directive, *pragma Restrictions*, that allows constraining the language features to a well-defined subset (for example, excluding dynamic OOP facilities).

The evolution of Ada has seen the continued increase in support for safety-critical and high-security applications. Ada 2005 standardized the Ravenscar profile, a collection of concurrency features that are powerful enough for real-time programming but simple enough to make certification and formal analysis practical. Ada 2012 introduced contract-based

[625] Common Criteria. *Common Criteria Development Board; *Common Criteria for Information Technology Security Evaluation (ISO/IEC 15408)*. Common Criteria, 2022. URL: https://www.commoncriteriaportal.org/.

programming facilities, allowing the programmer to specify preconditions and/or postconditions for subprograms, and invariants for encapsulated (private) types. These can serve both for run-time checking and as input to static analysis tools. The most recent version of the standard, Ada 2022, has added several contract-based programming constructs inspired by SPARK (`Contract_Cases`, `Global`, and `Depends` aspects) and, more generally, has enhanced the language's expressiveness. For example, Ada 2022 has introduced some new syntax in its concurrency support and has defined the Jorvik tasking profile, which is less restrictive than Ravenscar.

In brief, Ada is an internationally standardized language combining object-oriented programming features, well-engineered concurrency facilities, real-time support, and built-in reliability through both compile-time and run-time checks. As such it is an appropriate language for addressing the real issues facing software developers today. Ada has a long and successful history and is used throughout a number of major industries to design software that protects businesses and lives.

138.2 SPARK

SPARK is a software development technology (programming language and verification toolset) specifically designed for engineering ultra-low defect level applications, for example where safety and/or security are key requirements. SPARK Pro is AdaCore's commercial-grade offering of the SPARK technology. The main component in the toolset is GNATprove, which performs formal verification on SPARK code.

SPARK has an extensive industrial track record. Since its inception in the late 1980s it has been used worldwide in a range of industrial applications such as civil and military avionics, air traffic management / control, railway signaling, cryptographic software, and cross-domain solutions.

The SPARK language has been stable over the years, with periodic enhancements. The 2014 version of SPARK represented a major revision (see[626]), incorporating contract-based programming syntax from Ada 2012, and subsequent upgrades included support for pointers (access types) based on the Rust ownership model.

138.2.1 Flexibility

SPARK offers the flexibility of configuring the language on a per-project basis. Restrictions can be fine-tuned based on the relevant coding standards or run-time environments. SPARK code can easily be combined with full Ada code or with C, so that new systems can be built on and reuse legacy codebases.

138.2.2 Powerful Static Verification

The SPARK language supports a wide range of static verification techniques. At one end of the spectrum is basic data and control flow analysis, i.e., exhaustive detection of errors such as attempted reads of uninitialized variables, and ineffective assignments (where a variable is assigned a value that is never read). For more critical applications, dependency contracts can constrain the information flow allowed in an application. Violations of these contracts — potentially representing violations of safety or security policies — can then be detected even before the code is compiled.

In addition, the language supports mathematical proof and can thus provide high confidence that the software meets a range of assurance requirements: from the absence of run-time exceptions, to the enforcement of safety or security properties, to compliance with a formal specification of the program's required behavior.

[626] John W. McCormick and Peter C. Chapin. *Building High Integrity Applications with SPARK*. Cambridge University Press, 2015.

138.2.3 Ease of Adoption

User experience has shown that the language and the SPARK Pro toolset do not require a steep learning curve. Training material such as AdaCore's online AdaLearn course for SPARK[627] can quickly bring developers up to speed; users are assumed to be experts in their own application domain such as avionics software and do not need to be familiar with formal methods or the proof technology implemented by the toolset. In effect, SPARK Pro is an advanced static analysis tool that will detect many logic errors very early in the software life cycle. It can be smoothly integrated into an organization's existing development and verification methodology and infrastructure.

SPARK uses the standard Ada 2012 contract syntax, which both simplifies the learning process and also allows new paradigms of software verification. Programmers familiar with writing executable contracts for run-time assertion checking can use the same approach but with additional flexibility: the contracts can be verified either dynamically through classical run-time testing methods or statically (i.e., pre-compilation and pre-test) using automated tools.

SPARK supports *hybrid verification* that can mix testing with formal proofs. For example, an existing project in Ada and C can adopt SPARK to implement new functionality for critical components. The SPARK units can be analyzed statically to achieve the desired level of verification, with testing performed at the interfaces between the SPARK units and the modules in the other languages.

138.2.4 Reduced Cost and Improved Efficiency of Executable Object Code (EOC) verification

Software verification typically involves extensive testing, including unit tests and integration tests. Traditional testing methodologies are a major contributor to the high delivery costs for safety-critical software. Furthermore, they may fail to detect errors. SPARK addresses this issue by allowing automated proof to be used to demonstrate functional correctness at the subprogram level, either in combination with or as a replacement for unit testing (see *Property preservation between source code and object code* (page 2645)). In the high proportion of cases where proofs can be discharged automatically, the cost of writing unit tests is completely avoided. Moreover, verification by proofs covers all execution conditions and not just a sample.

138.3 GNAT Pro Assurance

GNAT Pro Assurance is an Ada and C development environment for projects requiring specialized support, such as bug fixes and *known problems* analyses, on a specific version of the toolchain. This product line is especially suitable for applications with long maintenance cycles or certification requirements, since critical updates to the compiler or other product components may become necessary years after the initial release. Such customized maintenance of a specific version of the product is known as a *sustained branch*.

Based on the GNU GCC technology, GNAT Pro Assurance supports all versions of the Ada language standard and also handles multiple versions of C (C89, C99, and C11). It includes an Integrated Development Environment (GNAT Programming Studio and/or GNATbench), a comprehensive toolsuite including a visual debugger, and an extensive set of libraries and bindings.

[627] AdaCore. *Online training for Ada and SPARK*. AdaCore. URL: https://learn.adacore.com/.

138.3.1 Sustained Branches

Unique to GNAT Pro Assurance is a service known as a *sustained branch*: customized support and maintenance for a specific version of the product. A project on a sustained branch can monitor relevant known problems, analyze their impact and, if needed, update to a newer version of the product on the same development branch (i.e., not incorporating changes introduced in later versions of the product).

Sustained branches are a practical solution to the problem of ensuring toolchain stability while allowing flexibility in case an upgrade is needed to correct a critical problem.

138.3.2 Configurable Run-Time Libraries

Two specific GNAT-defined run-time libraries have been designed with certification in mind and are known as the Certifiable Profiles:

- Light Profile
- Light-Tasking Profile

The Light Profile provides a flexible Ada subset that is supported by a certifiable Ada run-time library. Depending on application requirements, this profile can be further restricted through the `Restrictions` pragma, with the application only including run-time code that is used by the application.

These run-time libraries can also be customized directly to suit certification requirements: unneeded packages can be removed to allow for self-certification of the runtime, while the `-nostdlib` linker switch can be used to prevent the use of the runtime. Even when the run-time library is suppressed, some run-time sources are still required to provide compile-time definitions. While this code produces no object code, the certification protocol may still require tests to ensure correct access to these definitions.

The Light-Tasking Profile expands the Light Profile to include Ravenscar tasking support, allowing developers to use concurrency in their certification applications.

Although limited in terms of dynamic Ada semantics, all Certifiable Profiles fully support static Ada constructs such as private types, generic templates, and child units. Some dynamic semantics are also supported. For example, these profiles allow the use of tagged types (at library level) and other Object-Oriented Programming features, including dynamic dispatching. The general use of dynamic dispatching at the application level can be prevented through pragma `Restrictions`.

A traditional problem with predefined profiles is their inflexibility: if a feature outside a given profile is needed, then it is the developer's responsibility to address the certification issues deriving from its use. GNAT Pro Assurance accommodates this need by allowing the developer to define a profile for the specific set of features that are used. Typically this will be for features with run-time libraries that require associated certification materials. Thus the program will have a tailored run-time library supporting only those features that have been specified.

More generally, the configurable run-time capability allows specifying support for Ada's dynamic features in an *à la carte* fashion ranging from none at all to full Ada. The units included in the executable may be either a subset of the standard libraries provided with GNAT Pro, or specially tailored to the application. This latter capability is useful, for example, if one of the predefined profiles implements almost all the dynamic functionality needed in an existing system that has to meet new safety-critical requirements, and where the costs of adapting the application without the additional run-time support are considered prohibitive.

Certification material up to Software Level A can be developed for the Light and Light-Tasking run-time libraries.

138.3.3 Full Implementation of Ada Standards

GNAT Pro provides a complete implementation of the Ada language from Ada 83 to Ada 2012, and support for selected features from Ada 2022. Developers of safety-critical and high-security systems can thus take advantage of features such as contract-based programming, which effectively embed requirements in the source program text and simplify verification.

138.3.4 Source to Object Traceability

A compiler option can limit the use of language constructs that generate object code that is not directly traceable to the source code. As an add-on service, AdaCore can perform an analysis that demonstrates this traceability and justifies any remaining cases of non-traceable code.

138.3.5 Safety-Critical Support and Expertise

At the heart of every AdaCore subscription are the support services that AdaCore provides to its customers. AdaCore staff are recognized experts on the Ada language, software certification standards in several domains, compilation technologies, and static and dynamic verification. They have extensive experience in supporting customers in avionics, railway, space, energy, air traffic management/control, automotive, and military projects. Every AdaCore product comes with front-line support provided directly by these experts, who are also the developers of the technology. This ensures that customers' questions (requests for guidance on feature usage, suggestions for technology enhancements, or defect reports) are handled efficiently and effectively.

Beyond this bundled support, AdaCore also provides Ada language and tool training as well as on-site consulting on topics such as how to best deploy the technology, and assistance on start-up issues. On-demand tool development and ports to new platforms are also available.

138.3.6 Libadalang

Libadalang is a library, included with GNAT Pro, that gives applications access to the complete syntactic and semantic structure of an Ada compilation unit. This library is typically used by tools that need to perform some sort of static analysis on an Ada program.

AdaCore can assist customers in developing libadalang-based tools to meet their specific needs, as well as develop such tools upon request.

Typical libadalang applications include:

- Static analysis (property verification)
- Code instrumentation
- Design and document generation tools
- Metric testing or timing tools
- Dependency tree analysis tools
- Type dictionary generators
- Coding standard enforcement tools
- Language translators (e.g., to CORBA IDL)
- Quality assessment tools
- Source browsers and formatters
- Syntax directed editors

138.3.7 GNATstack

Included with GNAT Pro is GNATstack, a static analysis tool that enables an Ada/C software developer to accurately predict the maximum size of the memory stack required for program execution.

GNATstack statically predicts the maximum stack space required by each task in an application. The computed bounds can be used to ensure that sufficient space is reserved, thus guaranteeing safe execution with respect to stack usage. The tool uses a conservative analysis to deal with complexities such as subprogram recursion, while avoiding unnecessarily pessimistic estimates.

This static stack analysis tool exploits data generated by the compiler to compute worst-case stack requirements. It performs per-subprogram stack usage computation combined with control flow analysis.

GNATstack can analyze object-oriented applications, automatically determining maximum stack usage on code that uses dynamic dispatching in Ada. A dispatching call challenges static analysis because the identity of the subprogram being invoked is not known until run time. GNATstack solves this problem by statically determining the subset of potential targets (primitive operations) for every dispatching call. This significantly reduces the analysis effort and yields precise stack usage bounds on complex Ada code.

GNATstack's analysis is based on information known at compile time. When the tool indicates that the result is accurate, the computed bound can never be exceeded.

On the other hand, there may be cases in which the results will not be accurate (the tool will report such situations) because of some missing information (such as the maximum depth of subprogram recursion, indirect calls, etc.). The user can assist the tool by specifying missing call graph and stack usage information.

GNATstack's main output is the worst-case stack usage for every entry point, together with the paths that result in these stack sizes. The list of entry points can be automatically computed (all the tasks, including the environment task) or can be specified by the user (a list of entry points or all the subprograms matching a given regular expression).

GNATstack can also detect and display a list of potential problems when computing stack requirements:

- Indirect (including dispatching) calls. The tool will indicate the number of indirect calls made from any subprogram.
- External calls. The tool displays all the subprograms that are reachable from any entry point for which there is no stack or call graph information.
- Unbounded frames. The tool displays all the subprograms that are reachable from any entry point with an unbounded stack requirement. The required stack size depends on the arguments passed to the subprogram. For example:

```
procedure P(N : Integer) is
   S : String (1..N);
begin
   ...
end P;
```

- Cycles. The tool can detect all the cycles (i.e., potential recursion) in the call graph.

GNATstack allows the user to supply a text file with the missing information, such as the potential targets for indirect calls, the stack requirements for external calls, and the maximal size for unbounded frames.

TQL-5 qualification material can be made available for GNATstack.

138.4 CodeSonar for Ada

CodeSonar for Ada is a static analysis toolset that runs on Windows and Linux platforms and may be used with any standard Ada compiler or fully integrated into the GNAT Pro development environment.

138.4.1 Defects and vulnerability analysis

CodeSonar for Ada features an Ada source code analyzer that detects run-time and logic errors. It assesses potential bugs and vulnerabilities before program execution, serving as an automated peer reviewer, helping to find errors easily at any stage of the development life-cycle. It helps improve code quality and makes it easier to perform safety and/or security analysis. CodeSonar for Ada can detect several of the "Top 25 Most Dangerous Software Errors" in the Common Weakness Enumeration.

138.4.2 GNATmetric

The GNATmetric tool analyzes source code to calculate a set of commonly used industry metrics, thus allowing developers to estimate the size and better understand the structure of the source code. This information also facilitates satisfying the requirements of certain software development frameworks.

138.4.3 GNATcheck

GNATcheck is a coding standard verification tool that is extensible and rule-based. It allows developers to completely define a coding standard as a set of rules, for example a subset of permitted language features. It verifies a program's conformance with the resulting rules and thereby facilitates demonstration of a system's compliance with Table A-5, Objective 4 of DO - 178C/ED - 12C ("Source Code conforms to standards"). GNATcheck provides:

- An integrated *Ada Restrictions* mechanism for banning specific features from an application. This can be used to restrict features such as tasking, exceptions, dynamic allocation, fixed- or floating point, input/output and unchecked conversions.
- Restrictions specific to GNAT Pro, such as banning features that result in the generation of implicit loops or conditionals in the object code, or in the generation of elaboration code.
- Additional Ada semantic rules resulting from customer input, such as ordering of parameters, normalized naming of entities, and subprograms with multiple returns.
- An easy-to-use interface for creating and using a complete coding standard.
- Generation of project-wide reports, including evidence of the level of compliance with a given coding standard.
- Over 30 compile-time warnings from GNAT Pro that detect typical error situations, such as local variables being used before being initialized, incorrect assumptions about array lower bounds, infinite recursion, incorrect data alignment, and accidental hiding of names.
- Style checks that allow developers to control indentation, casing, comment style, and nesting level.

AdaCore's GNATformat tool, which formats Ada source code according to the GNAT coding style[619], can help avoid having code that violates GNATcheck rules.

GNATcheck comes with a query language (called LKQL) that lets developers define their own checks for any in-house rules that need to be followed. GNATcheck can thus be customized to meet an organization's specific requirements, processes and procedures.

[619] https://gcc.gnu.org/onlinedocs/gnat-style.pdf

TQL-5 qualification material is available for GNATcheck.

138.5 GNAT Dynamic Analysis Suite (GNAT DAS)

138.5.1 GNATtest

The GNATtest tool helps create and maintain a complete unit testing infrastructure for complex projects. Based on AUnit, it captures the simple idea that each public subprogram (these are known as *visible* subprograms in Ada) should have at least one corresponding unit test. GNATtest takes a project file as input, and produces two outputs:

- The complete harnessing code for executing all the unit tests under consideration. This code is generated completely automatically.
- A set of separate test stubs for each subprogram to be tested. These test stubs are to be completed by the user.

GNATtest handles Ada's Object-Oriented Programming features and can be used to help verify tagged type substitutability (the Liskov Substitution Principle) that can be used to demonstrate consistency of class hierarchies.

Testing a private subprogram is outside the scope of GNATtest but can be implemented by defining the relevant testing code in a private child of the package that declares the private subprogram. For DO - 178C/ED - 12C credit, such test code needs to be derived from the system's low-level requirements. Additionally, hybrid verification can help (see *Low-level verification by mixing test and proof ("Hybrid verification")* (page 2644)): augmenting testing with the use of SPARK to formally prove relevant properties of the private subprogram.

138.5.2 GNATemulator

GNATemulator is an efficient and flexible tool that provides integrated, lightweight target emulation.

Based on the QEMU technology, a generic and open-source machine emulator and virtualizer, GNATemulator allows software developers to compile code directly for their target architecture and run it on their host platform, through an approach that translates from the target object code to native instructions on the host. This avoids the inconvenience and cost of managing an actual board, while offering an efficient testing environment compatible with the final hardware.

There are two basic types of emulators. The first can serve as a surrogate for the final hardware during development for a wide range of verification activities, particularly those that require time accuracy. However, they tend to be extremely costly, and are often very slow. The second, which includes GNATemulator, does not attempt to be a complete time-accurate target board simulator, and thus it cannot be used for all aspects of testing. But it does provide a very efficient and cost-effective way to execute the target code very early in the development and verification processes. GNATemulator thus offers a practical compromise between a native environment that lacks target emulation capability, and a cross configuration where the final target hardware might not be available soon enough or in sufficient quantity.

138.5.3 GNATcoverage

GNATcoverage is a code coverage analysis tool. Its results are computed from trace files that show which program constructs have been exercised by a given test campaign. With source code instrumentation, the tool produces these files by executing an alternative version of the program, built from source code instrumented to populate coverage-related data structures. Through an option to GNATcoverage, the user can specify the granularity of the

analysis by choosing any of the coverage criteria defined in DO - 178C/ED - 12C: statement coverage, decision coverage, or Modified Condition / Decision Coverage (MC/DC).

Source-based instrumentation brings several major benefits: efficiency of tool execution (much faster than alternative coverage strategies using binary traces and target emulation, especially on native platforms), compact-size source trace files independent of execution duration, and support for coverage of shared libraries.

TQL-5 qualification material for GNATcoverage is available for DO - 178C/ED - 12C up to level A (MC/DC).

138.5.4 GNATfuzz

GNATfuzz is a fuzzing tool; i.e., a tool that automatically and repeatedly executes tests and generates new test cases at a very high frequency to detect faulty behavior of the system under test. Such anomalous behavior is captured by monitoring the system for triggered exceptions, failing built-in assertions, and signals such as SIGSEGV.

Fuzz testing has proven to be an effective mechanism for finding corner-case vulnerabilities that traditional human-driven verification mechanisms, such as unit and integration testing, can miss. Since such vulnerabilities can often lead to malicious exploitations, fuzzing technology is most useful for meeting security verification objectives as stated within DO - 326A/ED - 202A ("Airworthiness Security Process Specification") and more specifically the guidelines specified within DO - 356A/ED - 203A ("Airworthiness Security Methods and Considerations").

However, fuzz-testing campaigns are complex and time-consuming to construct, execute and monitor. GNATfuzz simplifies the process by analyzing a code base and identifying subprograms that can act as fuzz-test entry points. GNATfuzz then automates the creation of test harnesses suitable for fuzzing. In addition, GNATfuzz will automate the building, executing and analyzing of fuzz-testing campaigns.

Although GNATfuzz does not directly provide evidence for DO - 178C/ED - 12C compliance, it can serve a useful role if used as part of the software development and verification life cycle processes. For example, by detecting some of the anomalous behavior cited in §6.3.4.f (e.g., data corruption due to task or interrupt conflicts), GNATfuzz can help prevent defects from being introduced into the Source Code.

138.5.5 TGen

TGen is an experimental run-time library / marshalling technology that can be used by GNATtest and/or GNATfuzz to automate the production of test cases for Ada code. It performs type-specific low-level processing to generate test vectors for subprogram parameters, such as uniform value distribution for scalar types and analogous strategies for unconstrained arrays and record discriminants. A command-line argument specifies the number of test values to be generated, and these can then be used as input to test cases created by GNATtest.

TGen can also be used with GNATfuzz, to help start a fuzz-testing campaign when the user supplies an initial set of test cases where some may contain invalid data. GNATfuzz will utilize coverage-driven fuzzer mutations coupled with TGen to convert invalid test cases into valid ones. TGen represents test data values compactly, removing a large amount of memory padding that would otherwise be present for alignment of data components. With its space-efficient representation, TGen significantly increases the probability of a successful mutation that results in a new valid test case.

138.6 GNAT Pro for Rust

The Rust language was designed for software that needs to meet stringent requirements for both assurance and performance: Rust is a memory-safe systems-programming language with software integrity guarantees (in both concurrent and sequential code) enforced by compile-time checks. The language is seeing growing use in domains such as automotive systems and is a viable choice for airborne software.

AdaCore's *GNAT Pro for Rust* is a complete development environment for the Rust programming language, supporting both native builds and cross compilation to embedded targets. The product is not a fork of the Rust programming language or the Rust tools. Instead, *GNAT Pro for Rust* is a professionally supported build of a selected version of rustc and other core Rust development tools that offers stability for professional and high-integrity Rust projects. Critical fixes to *GNAT Pro for Rust* are upstreamed to the Rust community, and critical fixes made by the community to upstream Rust tools are backported as needed to the *GNAT Pro for Rust* code base. Additionally, the Assurance edition of *GNAT Pro for Rust* includes the "sustained branch" service (see *Sustained Branches* (page 2593)) that strikes the balance between tool stability and project flexibility.

138.7 Integrated Development Environments (IDEs)

138.7.1 GNAT Studio

GNAT Studio is a powerful and simple-to-use IDE that streamlines software development from the initial coding stage through testing, debugging, system integration, and maintenance. It is designed to allow programmers to get the most out of GNAT Pro technology.

Tools

GNAT Studio's extensive navigation and analysis tools can generate a variety of useful information including call graphs, source dependencies, project organization, and complexity metrics, giving a thorough understanding of a program at multiple levels. It allows interfacing with third-party version control systems, easing both development and maintenance.

Robust, Flexible and Extensible

Especially suited for large, complex systems, GNAT Studio can import existing projects from other Ada implementations while adhering to their file naming conventions and retaining the existing directory organization. Through the multi-language capabilities of GNAT Studio, components written in C and C++ can also be handled. The IDE is highly extensible; additional tools can be plugged in through a simple scripting approach. It is also tailorable, allowing various aspects of the program's appearance to be customized in the editor.

Easy to learn, easy to use

GNAT Studio is intuitive to new users thanks to its menu-driven interface with extensive online help (including documentation on all the menu selections) and *tool tips*. The Project Wizard makes it simple to get started, supplying default values for almost all of the project properties. For experienced users, it offers the necessary level of control for advanced purposes; e.g., the ability to run command scripts. Anything that can be done on the command line is achievable through the menu interface.

Remote Programming

Integrated into GNAT Studio, Remote Programming provides a secure and efficient way for programmers to access any number of remote servers on a wide variety of platforms while taking advantage of the power and familiarity of their local PC workstations.

138.7.2 VS Code Extensions for Ada and SPARK

AdaCore's extensions to Visual Studio Code (VS Code) enable Ada and SPARK development with a lightweight editor, as an alternative to the full GNAT Studio IDE. Functionality includes:

- Syntax highlighting for Ada and SPARK files
- Code navigation
- Error diagnostics (errors reported in the Problems pane)
- Build integration (execution of GNAT-based toolchains from within VS Code)
- Display of SPARK proof results (green/red annotations from GNATprove)
- Basic IntelliSense (completion and hover information for known symbols)

138.7.3 Eclipse support - GNATbench

GNATbench is an Ada development plug-in for Eclipse and Wind River's Workbench environment. The Workbench integration supports Ada development on a variety of VxWorks real-time operating systems. The Eclipse version is primarily for native applications, with some support for cross development. In both cases the Ada tools are tightly integrated.

138.7.4 GNATdashboard

GNATdashboard serves as a one-stop control panel for monitoring and improving the quality of Ada software. It integrates and aggregates the results of AdaCore's various static and dynamic analysis tools (GNATmetric, GNATcheck, GNATcoverage, SPARK Pro, among others) within a common interface, helping quality assurance managers and project leaders understand or reduce their software's technical debt, and eliminating the need for manual input.

GNATdashboard fits naturally into a continuous integration environment, providing users with metrics on code complexity, code coverage, conformance to coding standards, and more.

CHAPTER

NINE

COMPLIANCE WITH DO-178C/ED-12C GUIDANCE: ANALYSIS

139.1 Overview

DO - 178C/ED - 12C uses the term "requirement" to identify the expected behavior of the system, the software, or a part thereof. The desired functions are formulated at the system level as "system requirements" and are refined and elaborated into "software requirements". DO - 178C/ED - 12C identifies several categories of software requirements.

The High-Level Requirements (HLR) define the expected behavior of the complete software loaded on the target computer, independent of the software architecture. The HLR are further refined into one or more lower levels, specifying the expected behavior of each software subpart (component) based on the architecture definition. The lowest level of requirements (the LLR) and the architecture are translated into source code, which finally is compiled to produce the Executable Object Code (EOC).

Within this basic framework, the development process activities (requirements definition, design, coding, and integration) should be conducted so as to reduce the likelihood of introducing errors. Verification process activities are designed to detect errors through multiple filters, by assessing the same artifacts in different ways. This naturally applies to the EOC, whose verification involves checking compliance with the requirements at each level, using both normal and abnormal inputs. Such verification comprises manual reviews, automated analyses (possibly including the use of formal methods), and testing based on the software requirements. Finally, the EOC verification must itself be verified.

While it is not a DO - 178C/ED - 12C concept, a *V* cycle is often used to represent the complete software life cycle. A variation of the traditional *V* cycle, oriented around the DO - 178C/ED - 12C processes, was shown earlier in Fig. 1. As is seen in that figure, AdaCore tools mostly apply towards the bottom stages of the *V* cycle:

- Design (architecture + LLR), coding and integration (EOC generation), for the development activities.
- Design and source code review / analysis and LLR testing, for the verification activities.

Additional support is provided for design activities in conjunction with two technology supplements (Object-Oriented Technology and Formal Methods).

Language development environments provide the foundation for AdaCore's toolchains, including support for Ada, C, C++, and Rust. Complementary tools support several verification activities for Ada:

- GNATstack for stack checking (which also supports C),
- CodeSonar for Ada, providing defect and vulnerability detection, code standard checking (GNATcheck), and code metrics generation (GNATmetric)
- the GNAT Dynamic Analysis Suite, or GNAT DAS, for testing (GNATtest, TGen), structural code coverage analysis (GNATcoverage, which also supports C and C++), processor emulation (GNATemulator), and fuzzing (GNATfuzz).

To show how AdaCore tools can be used in connection with the software life cycle processes for a system that is to be assessed against DO - 178C/ED - 12C, several possible scenarios will be described:

- **Use Case 1: Traditional development process, excluding or including** OOT The development process produces requirements specified in text (natural language) that are implemented in Ada source code. A code standard defines a set of restrictions, which may or may not include limitations on object-oriented features. Both cases need to be considered:
  - Use Case 1a: No use is made of object oriented technology or related techniques
  - Use Case 1b: Ada's OOT features are used, and the guidance in DO - 332/ED - 217 is considered
- **Use Case 2: Using SPARK and Formal Methods** The development uses a formal description of the low-level requirements, namely SPARK / Ada 2012 contracts. A formal analysis is performed, and credit is claimed on reducing the testing. The certification effort follows the additional guidance from the Formal Methods Supplement (DO - 333/ED - 216).

In the tables that appear in this chapter, the references shown in parentheses for the objectives identify the table, objective number, and paragraph reference for the objective in the DO - 178C/ED - 12C standard or the relevant technology supplement. For example, A-2[6]: 5.3.1.a refers to Table A-2, Objective 6, paragraph 5.3.1a.

139.2 Use case #1a: Coding with Ada 2012

The adoption of Ada as the coding language brings a number of benefits during design, coding, and testing, both from language features (as summarized in the table below) and from the AdaCore ecosystem.

139.2.1 Benefits of the Ada language

	Contributions
Objectives	• Software Coding (A-2[6]: 5.3.1.a) • **Reviews and Analyses of Source Code:** – Verifiability (A-5[3]- 6.3.4.c) – Accuracy and consistency (A-5[6]- 6.3.4.f) • **Test Coverage Analysis:** – Test coverage for Data Coupling and Control Coupling achieved (A-7[8] - 6.4.4.d)
Activities	• Software Coding (5.3.2.a) • Reviews and Analyses of Source Code (6.3.4) • Structural Coverage Analysis (6.4.4.2.c, 6.4.4.2.d) • Structural Coverage Analysis Resolution (6.4.4.3)

Ada's most significant contribution is towards the reliability of the written code; the language is designed to promote readability and maintainability, and to detect errors early in the software development process. This section will summarize several Ada features that help meet these goals.

Modularization

Ada's package facility was designed for *programming in the large*: designing a system comprising millions of lines of code through modules (packages) that maximize reuse while making explicit the allowed inter-module dependencies. Ada directly supports the software engineering principle of *information hiding*, with a package comprising an interface (its specification) and an implementation (its body). A package specification itself is separated into a *visible part* that is accessible externally, and optionally a *private part* that can only be accessed by the associated package body and by the private parts and bodies of child packages. Packages support programming by composition (bottom-up design), programming by decomposition (top-down design), and programming by extension (Object-Oriented Programming).

Packages make clear syntactically, and enforce with compile-time checks, the ways in which one module can depend on another; in DO - 178C/ED - 12C terms, their coupling. They thus help meet the DO - 178C/ED - 12C objective A-7[8] of achieving test coverage of the system's control and data coupling. For example, if a compilation unit `Q` has a **`with`** dependence on package `P`, then `Q` has a potential data coupling on any data item defined in the visible part of the specification for `P`, and likewise a potential control coupling on any subprogram defined in the visible part of the specification for `P`. These couplings are actualized if `Q` references these items, and they must be demonstrated by structural code coverage tests. On the other hand, data items or subprograms defined in `P`'s private part or package body are inaccessible to `Q` (any such accesses would be flagged as compile-time errors), and thus they do not constitute a coupling for `Q`. For further details, see *Data and control coupling coverage with GNATcoverage* (page 2625).

Strong typing

The emphasis on early error detection and program clarity is perhaps most clearly illustrated in the language's *strong typing*. A type in Ada is a semantic entity that can embody static (and possibly also dynamic) constraints. For example:

```
type Ratio is digits 16 range -1.0 .. 1.0;
```

In the above example, `Ratio` is a floating-point type. Two constraints are specified:

- **`digits`** specifies the minimum precision needed for objects of this type, in terms of decimal digits. Here the compiler will likely choose a 64-bit representation. If the target architecture only supports 32-bit floating-point, the compiler will reject the program.
- **`range`** defines the set of acceptable values. Here, only values between `-1.0` and `1.0` (inclusive) are acceptable; an attempt to assign a value outside this range to a variable of type `Ratio` will raise the `Constraint_Error` run-time exception.

Strong typing means an absence of implicit conversions (implicit *casts*), since such conversions can mask logical errors. For example:

```
type Miles      is digits 16;
type Kilometers is digits 16;
...
Distance_1 : Miles;
Distance_2 : Kilometers;
...
Distance_1 := Distance_2; -- Illegal, rejected at compile time
```

Both `Miles` and `Kilometers` are 16-digit floating-point types (the range constraint is optional in a floating-point type declaration) but they are different types, and thus the assignment is illegal. Likewise, it is illegal to combine `Miles` and `Kilometers` in an expression; `Miles + Kilometers` would also be rejected by the compiler.

With strong typing the program's data can be partitioned so that an object of a given type can only be processed using operations that make sense for that type. This helps prevent

data mismatch errors.

Explicit conversions between related types are allowed, either predefined (for example between any two numeric types) or supplied by the programmer. Explicit conversions make the programmer's intent clear. For example:

```
type Grade is range 0..100;  -- a new integer type

Test_Grade : Grade;
N          : Integer;        -- predefined type
...
Test_Grade := N;
  -- Illegal (type mismatch), rejected at compile time

Test_Grade := Grade (N);
  -- Legal, with run-time constraint check that N is in 0..100
```

Dimensionality checking

One of the challenges to a language's type model is the enforcement of the proper use of units of measurement. For example dividing a distance by a time should be allowed, yielding a velocity. But the error of dividing a time by a distance where a velocity value is required should be detected and reported as an error at compile time.

Although this issue could be addressed in theory by defining a separate type for each unit of measurement, such an approach would require defining functions (likely as overloaded operator symbols) for the permitted operand combinations. This would be notationally cumbersome and probably not used much in practice.

The GNAT Pro environment provides a solution through the implementation-defined aspects `Dimension_System` which can be applied to a type, and `Dimension` which can be applied to a subtype. Uses of variables are checked at compile time for consistency based on the `Dimension` aspect of their subtypes. The GNAT library includes a package `System.Dim.Mks` that defines a type and its associated subtypes that will be used for meters (`Length`), kilograms (`Mass`), seconds (`Time`), and other units. The programmer can define a subtype such as `Velocity` that corresponds to `Length` (in meters) divided by `Time` (in seconds):

```
subtype Velocity is Mks_Type with
Dimension => ("m/sec",
              Meter  => 1,
               -- Values are exponents in the product of
               -- the units
              Second => -1,
              others => 0);
```

With such a declaration the following is permitted:

```
My_Distance : Length    := 10 * m;   -- m is 1.0 meter
My_Time     : Time      := 5.0 * h;  -- h is 1.0 hour
                                     -- (3600.0 sec)
My_Velocity : Velocity  := My_Distance / My_Time; -- OK
```

A `Velocity` value should be computed as a distance divided by a time. The following will be detected as an error:

```
My_Distance : Length    := 10 * m;
My_Time     : Time      := 5.0 * h;
My_Velocity : Velocity  := My_Time / My_Distance;  -- Illegal
```

GNAT Pro's support for dimensionality checking is a useful adjunct to Ada's strong typing facilities.

Pointers

For compliance with DO - 178C/ED - 12C, the use of dynamic memory (and pointers) should be kept to the bare minimum, and Ada helps support this goal. Features such as arrays or by-reference parameter passing, which require pointers or explicit references in other languages, are captured by specific facilities in Ada. For example, Ada's parameter passing mechanism reflects the direction of data flow (in, out, or in out) rather than the implementation technique. Some data types always require by-copy (for example scalars), and some types always require by-reference (for example tagged types, in OOP). For all other types the compiler will choose whether it is more efficient to use by-reference (via a hidden pointer or reference) or by-copy. Since the developer does not have to explicitly manipulate pointers to obtain by-reference passing, many common errors are avoided. Here's an example:

```
type Rec is
   record
      A, B : Integer;
   end record;

My_Rec : Rec;

procedure Update (R : in out Rec);

...

Update (My_Rec);
```

The above procedure takes a Rec object as an **in out** parameter. In the invocation `Update (My_Rec)`, the compiler may choose to pass My_Rec either by reference or by copy based on efficiency considerations. Other languages use pointers, either explicitly or implicitly, to obtain by-reference passing if the actual parameter needs to be modified by the called subprogram.

When pointers are absolutely required, Ada's approach is to supply a type-safe and high-level mechanism (known as *access types*) to obtain the needed functionality while also providing low-level facilities that are potentially unsafe but whose usage is always explicitly indicated in the source text (thus alerting the human reader).

One example is the use of the generic procedure `Ada.Unchecked_Deallocation` to free the storage for an object that is no longer needed:

```
with Ada.Unchecked_Deallocation;
procedure Proc is
   type String_Ptr is access String;
   procedure Free is new Ada.Unchecked_Deallocation (String, String_Ref);
   -- procedure Free (X : in out String_Ref);
   Ptr : String_Ptr;
begin
   ...
   Ptr := new String' ("Hello");
   -- Allocates a String, initialized to "Hello"
   ...
   Free (Ptr);
   -- Deallocates heap object, sets Ptr to null
   ...
end Proc;
```

An object of type `String_Ptr` is a value that is either **null** or else points to a dynamically allocated **String** object. To deallocate an allocated object, it is necessary to instantiate the generic procedure `Ada.Unchecked_Deallocation`; the result is the definition of procedure `Free`. The sample code allocates an initialized heap object and subsequently frees its storage.

As another example, here's a C code fragment that performs pointer arithmetic:

```
int *ptr = malloc (sizeof (int));
ptr++;
```

This may or may not be safe; after the increment, `ptr` points to a location immediately beyond the storage for the allocated **int**.

As part of its C interfacing facilities Ada supports such pointer arithmetic, indeed with algorithmic code that is similar to the C notation, but the dependence on a potentially unsafe operation is explicit:

```
with Interfaces.C.Pointers;
procedure Pointer_Arith is
   type Int_Array is
     array (Positive range <>) of aliased Integer;

   package P is
     new Interfaces.C.Pointers(Positive, Integer,
                               Int_Array, Integer'First);
   -- This generic instantiation defines the access type
   -- Pointer and its associated operations
   use type P.Pointer;
   -- For notational convenience in invoking "+"

   Ref  : P.Pointer := new Integer;
begin
   Ref  := Ref+1;
   -- Increments Ref by the size (number of storage elements)
   -- of an Integer
end Pointer_Arith;
```

This syntax, though wordier than the C version, makes potentially unsafe operations much more visible, hence easier to identify and review.

Arrays

The array (an indexable sequence of elements) is a fundamental and efficient data structuring mechanism, but a major vulnerability unless attempted accesses to data outside the bounds of the array are prevented. Ada avoids this vulnerability since array operations such as indexing are checked to ensure that they are within the specified bounds. In addition to indexing, Ada provides various array operations (assignment, comparison, slicing, catenation, etc.) which allow manipulating arrays in an explicit and safe manner.

Ada's arrays are *fixed size*; once an array object is created, its bounds are established and cannot change. This simplifies the storage management (arrays in Ada can go on the stack and do not require hidden pointers). Additional flexibility (for example bounded-size arrays whose length can vary up to a specified maximum limit, or unbounded arrays of arbitrary length) is obtained through the Ada predefined library.

Here's an example:

```
type Int_Array is array(Positive range <>) of Integer;
-- Different objects of type Int_Array can have different
-- bounds

A : Int_Array (1 .. 8);
B : Int_Array (2 .. 12);
I : Integer;
...

A := (others => 0);
```

(continues on next page)

(continued from previous page)

```
B := (2 .. 7 => 0, others => 1);
...
if A (1 .. 3) = B (6 .. 8) then
   Put_Line ("Slices are equal");
end if;

Get (I);        -- Read in an integer
A (I) := 100;   -- Run-time check that I is in range
```

The above code creates two arrays, A with 8 elements indexed from 1 to 8, and B with 11 elements indexed from 2 to 12. A is assigned all zeroes, and B is assigned 0 in its first 6 elements and 1 in the rest. Contiguous sequences (slices) of the two arrays are compared for equality. All of this is done through standard language syntax as opposed to explicit loops or library calls.

The code at the end of the example illustrates Ada's index checking. If I is not in the index range of array A (i.e., between 1 and 8 inclusive) then a run-time exception (Constraint_Error) is raised.

Other Ada features

Many other features contribute to Ada's support for reliable and maintainable embedded software. Some were described briefly in *Language Overview* (page 2588). Others include the Ravenscar profile, a deterministic tasking subset that is simple enough for certification but rich enough to program real-time embedded systems; and Ada's low-level facilities, which allow the programmer to specify target-specific representations for data types (including the bit layout of fields in a record, and the values for enumeration elements). Further information on features that contribute to safe software may be found in[628].

In summary, Ada's benefits stem from its expressive power, allowing the developer to specify the needed functionality or to constrain the feature usage to a deterministic subset, together with its support for reliability and readability. A variety of errors, including some of the most frequent and harmful vulnerabilities, are detected in Ada either at compilation time or through dynamic checks automatically added by the compiler. Such checks can be either retained (for example during a testing campaign) or removed (for example at production time, after verification has provided confidence that they are not needed).

Additional Ada features will be described and highlighted in other sections of this document.

139.2.2 Using Ada during the design process

[628] John Barnes and Ben Brosgol. *Software, an invitation to Ada 2012*. AdaCore, 2015. URL: https://www.adacore.com/books/safe-and-secure-software.

An application's design — that is its low-level requirements and software architecture — may be specified in many ways, combining text and graphics at various levels of formality. The main principle is to keep the design at a higher level of abstraction than the code: in particular avoiding expression of requirements as code or pseudo-code. Requirements are properties to be verified by the code and are not the code itself. Thus the general advice is to avoid using a programming language as the medium for expressing — even in part — the software design.

Ada, however, presents an exception to this advice. The language provides extensive facilities for capturing a program unit's specification (its *what*) separately from the implementation (its *how*). An Ada package and an Ada subprogram each consists of a specification (the interface) and a body (the implementation) and a similar separation of interface from implementation is found in generic units, tasks, and encapsulated types.

A unit's specification establishes the constraints on its usage, that is, the permitted relationships between that unit and other parts of the program. These are the unit's architectural properties, in contrast to its implementation. It thus makes sense for a significant part of the Ada specifications to be developed during the design process. An interesting effect is that the design elements defined as Ada specifications are easy to verify, sometimes simply by compiling the code and showing that the interface usages are correct.

The separation of specification and implementation means that an Ada specification can have an implementation written in a different language, for example C. Although this may lose some of Ada's benefits, it illustrates the flexibility and relevance of the approach.

Component identification

Regardless of the method used for designing the software as a hierarchical set of components, Ada may be directly used to identify the software components and define their interfaces. This is typically done via package specifications and subprogram specifications.

A few comments on the term *interface* may be helpful. (It is not referring to the OOP language feature here.) Informally, a component's interface is the collection of its properties that establish whether any given usage of the component is correct. These properties arise at several levels. As an example, for a procedure that sorts an array of floating point values its interface may be regarded as comprising the following:

- Syntactic interface: the procedure's name and its formal parameters (their names, parameter passing modes, and types).
- Information flow interface: how, if at all, non-local data are accessed by the procedure (read, written, or both)
- Semantic (functional) interface: the function performed by the procedure — what does it mean to sort an array, independent of the algorithm — which is a low-level requirement for the procedure

Other low-level constraints may also be considered as part of the interface, such as a time or space constraint.

The syntactic interface in Ada is a simple subprogram specification:

```
type Float_Array is array (Integer range <>) of Float;

procedure Sort (My_Array : in out Float_Array);
```

This will also suffice for information flow if Sort does not access non-local data. If Sort does access non-local data then the uses can be specified informally by comments:

```
type Float_Array is array (Positive range <>) of Float;

procedure Sort (My_Array : in out Float_Array);
```

(continues on next page)

(continued from previous page)

```
-- Inputs: None
-- Outputs
-- p_GLOBAL.Status : p_GLOBAL.T_Status;
```

They can also be captured more formally as *aspects* of the procedure specification (an aspect is a technical feature that specifies a property of a program entity) if the SPARK subset of Ada is used, as will be explained below.

The LLR (including the semantic interface) are developed in parallel and may be specified separately from or together with the component's specification. They can be defined in natural language, as comments, or using contracts (pre- and/or postconditions) as illustrated in the next subsection.

Low-Level Requirements

A simple example of a low-level requirement, for the `Sort` procedure defined above, is the following:

> *The component shall order the array from the smallest value to highest one*

In Ada, we can capture this requirement as a postcondition aspect of the procedure:

```
type Some_Array is array (Positive range <>) of Integer;

procedure Sort (My_Array : in out Some_Array)
with Post =>
   (for all I in My_Array'First .. My_Array'Last-1 =>
                  My_Array (I) <= My_Array (I+1) );
```

The **`with`** `Post` construct defines a postcondition for the procedure; i.e., a condition that is asserted to be **`True`** when the procedure returns. Here it expresses, in Ada syntax, the low-level requirement that the procedure sort the array in ascending order: for each index `I` into the array, from the first position through the next-to-last, the value of the element at position `I+1` is at least as large as the element at position `I`. In the degenerate case where the array is either empty or contains a single element (i.e., when the range of `I` is empty) the **`for all`** condition is considered to be **`True`**.

It's clear that the postcondition expression says nothing about how the procedure is implemented. It's not pseudo-code for an algorithm but rather a property of the procedure that will need to be verified. It's the formalization of a requirement that happens to use Ada syntax. Moreover, a postcondition can refer to the values of formal parameters and/or global data, both at the point of call and the point of return. (In the above example, the postcondition could be strengthened by specifying that the value of `My_Array` on return is a permutation, possibly the identity mapping, of the value on entry.) And a function postcondition can refer to the value being returned by the function.

A subprogram can also have a precondition (a Boolean expression), which is a requirement that the caller needs to satisfy and that is assumed to be **`True`** by the called subprogram. For example, a function that returns the maximum value in an array of integers should have a precondition that the array is non-empty. The postcondition that is shown reflects the two properties that need to be met:

- The function result is at least as large as each element in the array, and
- The function result is present in the array

```
type Some_Array is array (Positive range <>) of Integer;

function Maximum (My_Array : in Some_Array) return Integer
 with Pre  => My_Array'Length > 0,
      Post =>
```

(continues on next page)

(continued from previous page)

```
          (for all I in My_Array'Range =>
               Maximum'Result >= My_Array (I)) and
          (for some I in My_Array'Range =>
               Maximum'Result = My_Array (I));
```

Preconditions and postconditions, and related features such as type invariants, are referred to collectively as *contract-based programming* and were introduced in the Ada 2012 version of the language. Based on the assertion policy (as specified by a pragma), the contracts can be checked at run-time, raising an exception on failure. They also support (but do not require) formal analysis, since the Ada syntax is the same as is used in SPARK. In SPARK the contracts are subject to additional restrictions (for example they must conform to the SPARK language subset). The contracts are then considered to be low-level requirements and verification cases at the same time, used by the SPARK proof technology for formal verification, for example to demonstrate that if a subprogram satisfies its precondition then on return it will satisfy its postcondition. In summary, functional contracts (such as pre- and postconditions) serve three purposes:

- As conditions to be formally proved by SPARK technology,
- As run-time conditions to be evaluated/checked using standard Ada semantics, and
- As requirements documentation to the human reader (if checks are not enabled and formal methods are not used) in an unambiguous notation (i.e., using Ada syntax rather than natural language)

When used for defining the software's architecture, Ada specifications can obviously express concepts such as modules (packages), groups of modules (package hierarchies), subprograms, class inheritance hierarchies, etc. Additional interface properties can be expressed using SPARK aspects, for example a subprogram's data and flow dependencies. Here's an example which, for simplicity and purposes of illustration, uses visible variables in a package specification to represent a data structure for a last-in first-out stack:

```
package Stack_Pkg is

   Max_Length : constant := 100;
   subtype Element_Type is Integer;

   Length     : Natural range 0.. Max_Length := 0;
   Stack      : array (1..Max_Length) of Element_Type);

   procedure Push ( Item : in Element_Type )
   with Global  => (In_Out => (Length, Stack)),
        Depends => (Length => Length,
                    Stack  => (Stack, Length, Item)),
        Pre     => Length < Max_Length,
        Post    => Length = Length'Old+1;
   ...
end Stack_Pkg;
```

The `Global` aspect captures the data dependency: `Push` will reference and assign to the global variables `Length` and `Stack`. The `Depends` aspect captures the flow dependency: the new value of `Length` depends on its old value, and the new value of `Stack` depends on the values of `Stack`, `Length`, and `Item`. These dependencies can be verified by the SPARK tools (assuming that the subprogram body is written in the SPARK subset). The pre- and postconditions reflect some of the functional properties of the procedure, and the postcondition illustrates the `'Old` attribute for referencing the point-of-call value of a variable.

A more realistic version of this example would hide the representation in the private part or body of the package. The contracts would then be expressed differently, for example with the Global and Depends referring to the abstract state of the package rather than visible

variables.

Some low-level requirements might not be expressible using the aspect mechanism (for example timing constraints). A convenient approach during architecture definition is to separately specify those components whose requirements can be defined using contracts, from those that cannot.

Implementation of Hardware / Software Interfaces

Ada's type system makes it straightforward to implement hardware/software interfaces, while also detecting target incompatibilities at compile time. Such interfaces may be defined as part of the coding process, but performing this activity during the design process has a number of benefits. It may avoid duplication of effort and also helps prevent errors from being introduced during the translation from design to code. It also allows early error detection through compilation checks.

Package Interfaces

Applications sometimes need to use types that correspond exactly to the native numeric data representations supported on the target machine, for example 16- or 32-bit signed and unsigned integers. Such types are defined in package `Interfaces`, which is part of the standard Ada library. The exact set of types depends on the target but typically includes integer types such as `Unsigned_16`, `Unsigned_32`, `Integer_16`, and `Integer_32`, as well as several floating-point types. The unsigned integer types are especially useful for hardware / software interfacing since they support bitwise operations including shift and rotate functions.

Specifying data representation

Embedded systems often need to deal with external data having a specific representation, and Ada has a variety of features to help meet this requirement. For example, the following can be defined:

- the values of the elements in an enumeration type,
- the layout of a record (size and position of each field, possibly with fields overlaid), and
- the address, size, and/or alignment of a data object.

The compiler will check that the specified representation is consistent with the target hardware. For example, Fig. 3 shows the required layout (on a *little-endian* machine) for a data object consisting of an unsigned 16-bit integer (`Num`), a 4-bit enumeration value (`Urgency`) that is either `Low`, `Medium`, or `High`, with the respective values 2, 5, and 10), and a Boolean flag (F).

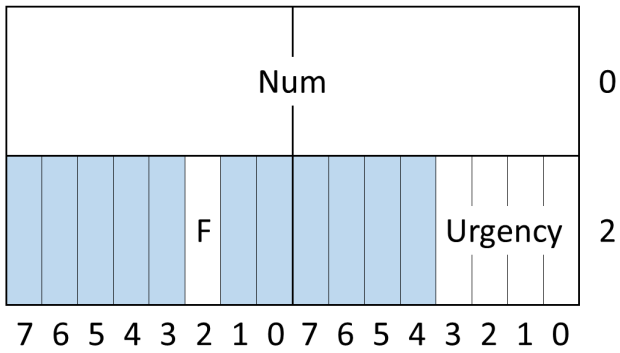

Fig. 3: Data Layout

As with other entities, Ada separates the type's *interface* (its logical structure as a record type with named fields) from its *implementation* (its physical representation / layout including size, alignment, and exact position of each field). The representation can be specified through a combination of aspects and representation clauses. Defining the `Bit_Order` and the `Scalar_Storage_Order` explicitly means that the code will work correctly on both little-endian and big-endian hardware.

```
type Urgency_Type is (Low, Medium, High);
for Urgency_Type use (Low => 2, Medium => 5, High => 10);
for Urgency_Type'Size use 4; -- Number of bits
type Urgency_Type is (Low, Medium, High);
for Urgency_Type use (Low => 2, Medium => 5, High => 10);
for Urgency_Type'Size use 4; -- Number of bits

type Message is
   record
      Num     : Interfaces.Unsigned_16;
      Urgency : Urgency_Type;
      F       : Boolean;
   end record
with
   Bit_Order            => System.Low_Order_First,
   Scalar_Storage_Order => System.Low_Order_First,
      -- Scalar_Storage_Order is a GNAT-specific aspect
   Size                 => 32, -- Bits
   Alignment            => 4;  -- Storage units

for Message use   -- Representation clause
   record
      Num     at 0 range 0..15;
      Urgency at 2 range 0..3;
      F       at 3 range 2..2;
   end record;
```

The **at** syntax in the record representation clause specifies the offset (in storage units) to the storage unit where the field begins, and the bit positions that are occupied. A field can overlap multiple storage units.

When the program specifies these kinds of representational details, it's typical for the application to read a *raw* value from an external source, and in such cases it is important to ensure that such data values are valid. In the above example, the `Urgency` field needs to have one of the values 2, 5, or 10. Any other value has to be detected by the program logic, and Ada's `'Valid` attribute can perform that check. The following example illustrates a typical style:

```
M : Message;
...
Device.Read (M);  -- Reads a value into M
if not M.Urgency'Valid then
   ... -- Report non-valid input value
else
   ... -- Normal processing
end if;
```

The 'Valid attribute can be applied to data objects from numeric and enumeration types. It is useful when the permitted values for the object are a proper subset of the full value set supported by the object's representation.

Numeric types

Another feature related to hardware/software interfaces is Ada's numeric type facility (integer, floating-point, fixed-point). The programmer can specify the type's essential properties, such as range and precision, in a machine-independent fashion; these will be mapped to an efficient data representation, with any incompatibilities detected at compile time. As an example:

```
type Nanoseconds is range 0 .. 20_000_000_000;

V : Nanoseconds;
```

The above code requires integers up to 20 billion to be represented. This would only be accepted on a 64-bit machine, and the compiler would reject the program if the target lacks such support. This can even be made explicit as part of the type declaration:

```
type Nanoseconds is range 0 .. 20_000_000_000
with Size => 64;

V : Nanoseconds;
```

The compiler will check that 64 bits are sufficient, and that it can be implemented on the target computer.

Similar constraints can be expressed for floating-point types:

```
type Temperature is digits 14;

V : Temperature;
```

At least 14 digits of decimal precision are required in the representation of Temperature values. The program would be accepted if the target has a 64-bit floating point unit, and would be rejected otherwise.

139.2.3 Integration of C components with Ada

	Contributions
Objectives	• Software Coding (A-2[6]: 5.3.1.a) • Software Integration (A-2[7]: 5.4.1.a)
Activities	• Software Coding (5.3.2.a) • Software Integration (5.4.2a)

C is widely used for embedded development, including safety-critical systems. Even where Ada is the main language for a system, components written in C are very commonly included, either from legacy libraries or third party software. (Languages such as Java and

C++ are used much less frequently. This is due in part to their semantic complexity and the difficulty of demonstrating compliance with certification standards, for example for the C++ standard library or the Java Garbage Collector.)

Friendly cooperation between Ada and C is supported in several ways by AdaCore tools and the Ada language.

- Most of the tools provided by AdaCore (compiler, debugger, development environments, etc.) can support systems written entirely in Ada, in a mixture of Ada and C, and entirely in C.
- Specific interfacing tools are available to automatically generate bindings between Ada and C, either creating Ada specification from a C header file:

  ```
  $ g++ -fdump-ada-spec
  ```

  or a C header file from an Ada specification:

  ```
  $ gcc -gnatceg
  ```

  These binding generators make it straightforward to integrate C components in an Ada application or vice versa.
- The Ada language directly supports interfacing Ada with other languages, most notably C (and also Fortran and COBOL). One of the standard libraries is a package `Interfaces.C` that defines Ada types corresponding to the C basic types (`int`, `char`, etc.) and implementation advice in the Ada Language Reference Manual explains how to import C functions and global data to be used in Ada code, and in the other direction, how to export Ada subprograms and global data so that they can be used in C.
- The GNAT Pro compiler uses the same back end technology for both Ada and C, facilitating interoperability.
- A project using a C codebase can incrementally introduce Ada or SPARK. Ada has standard support for interfacing with C, SPARK can be combined with C (with checks at the interfaces)[629], and AdaCore's GNAT Pro Common Code Generator compiles a SPARK-like subset of Ada into C (for use on processors lacking an Ada compiler). C projects can thus progressively adopt higher-tier languages without losing the investment made in existing components.

139.2.4 Robustness / defensive programming

	Contributions
Objectives	• Software Coding (A-2[6]: 5.3.1.a) • Reviews and Analyses of Source Code: Accuracy and consistency (A-5[6]: 6.3.4.f)
Activities	• Software Coding (5.3.2.a) • Software Coding (5.3.2.c - inadequate/incorrect inputs) • Reviews and Analyses of Source Code (6.3.4) • Robustness Test Cases (6.4.2.2)"

Robustness means ensuring correct software behavior in the presence of abnormal input, and (as per DO - 178C/ED - 12C) such behavior should be defined in the software requirements. There is no fundamental difference between requirements concerning abnormal input (robustness requirements) and those concerning normal input (functional requirements).

[629] Johannes Kanig, Quentin Ochem, and Cyrille Comar. *Bringing SPARK to C developers*. ERTS, 2016.

One approach to meeting robustness requirements is through defensive programming techniques; that is, code that detects incorrect input and performs the appropriate actions. However, this has two undesirable side effects.

- "Correct behavior in case of incorrect input" is sometimes difficult to define, resulting in code that cannot be verified by requirements based tests. Additional test cases based on the code itself (called *structural testing*) are not acceptable from a DO - 178C/ED - 12C perspective, since they are not appropriate for revealing errors.
- Unexercised defensive code complicates structural coverage analysis. It can't be classified as *extraneous* (since it does meet a requirement), but neither can it be considered as *deactivated* (since it is intended to be executed when the input is abnormal). As with any other non-exercised code, justification should be provided for defensive code, and this may entail difficult discussions with certification authorities.

An alternative approach is to ensure that no invalid input is ever supplied (in other words, to make each caller responsible for ensuring that the input is valid, rather than having the callee deal with potential violations). This can be done through the use of Ada 2012 contracts. Here's an example, a procedure that interchanges two elements in an array:

```
type Float_Array is array (1..100) of Float;

procedure Swap (FA     : in out Float_Array;
                I1, I2 : in Integer);
-- I1 and I2 have to be indices into the array,
--  i.e., in FA'Range

procedure Swap (FA     : in out Float_Array;
                I1, I2 : in Integer) is
   Temp : Float;
begin
   if I1 in FA'Range and then I2 in FA'Range then
      Temp    := FA (I1);
      FA (I1) := FA (I2);
      FA (I2) := Temp;
   end if;
end Swap;
```

The above example illustrates the ambiguity of the requirements for defensive code. What does it mean to invoke Swap when one or both indices are out of range? Not doing anything (which is the effect of the above code) is a possible answer, but this should be identified as a derived requirement (since it is an additional behavior of the component). Other possibilities:

- Raise an exception
- Report the error through an additional **out** parameter to the procedure, or as a status value returned (if the subprogram were expressed as a function rather than a procedure)
- Map an out-of-bounds low value to FA'First, and an out-of-bounds high value to FA'Last

Even if one of these options is chosen as the required behavior, there are both efficiency questions (why should the procedure spend execution time checking for a condition that is expected to be met) and methodological issues with such defensive code.

The responsibility should really be on the caller to avoid invoking the procedure if any of the actual parameters has an incorrect value. A comment in the code states that the indices should be in range, but Ada 2012 allows formalizing this comment in an automatically verifiable way:

```
type Float_Array is array (Positive range <>) of Float;

procedure Swap (FA : in out Float_Array; I1, I2 : Integer)
   with Pre => I1 in FA'Range and then I2 in FA'Range

procedure Swap (FA : in out Float_Array; I1, I2 : Integer) is
   Temp : Float;
begin
   Temp    := FA (I1);
   FA (I1) := FA (I2);
   FA (I2) := Temp;
end Swap;
```

The comment has been replaced by a precondition, which is part of the procedure specification. Assuming proper verification at each call site, defensive code in the implementation of the procedure is not needed. The requirement is now to check that the values passed at each call meet the precondition, and to take appropriate action if not. This action may differ from call to call, and may involve further preconditions to be defined higher up in the call chain.

Enforcement of these preconditions may be accomplished through several possible activities:

- **Code reviews using the Ada contracts as constraints**. This is the least formal technique, but the explicit specification of the preconditions in Ada contract syntax (versus comments) helps improve the thoroughness of the review and avoids the potential ambiguity of requirements expressed in natural language.
- **Enabling dynamic checks during testing, and removing them in the final executable object code**. Run-time checks are generated for pre- and postconditions if the program specifies `pragma Assertion_Policy (Check)` and the code is compiled with the compiler switch `-gnata`. A violation of a pre- or postcondition will then raise the `Assertion_Error` exception. After testing and related verification activities achieve sufficient assurance that no violations will occur, the checking code can be removed (either by `pragma Assertion_Policy(Ignore)` or by compiling without `-gnata`).
- **Enabling dynamic checks during testing, and keeping them in the final executable object code**. In this case, the software requirements should define the expected behavior in case a pre- or postcondition is violated, for example to reset the application to a known safe state as soon as an inconsistency is detected.
- **Static analysis or formal proof**. *CodeSonar for Ada* (page 2596) takes preconditions into account as part of its analysis in detecting potential errors. It can be tuned based on whether the priority is on finding as many errors as possible, at the expense of false positives, or on "picking the low-hanging fruit": detecting defects but minimizing the false positives at the expense of missing some actual errors. The *SPARK* (page 2591) tools likewise use preconditions, in this case to guide formal analysis. The proof engine can statically verify (or else report otherwise) that (1) a precondition is strong enough to guarantee the absence of run-time errors in the subprogram, and (2) every call satisfies the precondition. The SPARK analysis is sound (no false negatives): if the proof succeeds, then there is no violation of the properties that SPARK checks for.

The methods and activities adopted to address the robustness issue should be described in the software plans and, when applicable, in the software development standards (requirements and/or code standards).

Note that pre- or postcondition contracts do not in themselves implement robustness requirements. Instead they help to formalize and verify such requirements (through static analysis, formal proof, and/or testing). The defensive code is the code that is developed, if any, to make sure that these contracts are respected.

139.2.5 Defining and Verifying a Code Standard with GNATcheck

	Contributions
Objectives	• Software Planning Process (A-1[5]: 4.1.e) • Software Coding (A-2[6]: 5.3.1.a) • Reviews and Analyses of Source Code (A-5[4]: 6.3.4.d)
Activities	• Software Planning Process Activities (4.2.b) • Software Development Standards (4.5.b, 4.5.c) • Software Coding (5.3.2.b) • Reviews and Analyses of Source Code (6.3.4)

Defining a Software Code Standard serves at least two purposes:

- It helps to make the application source code consistent, more verifiable, and more easily maintainable. While these qualities do not have a direct safety benefit, adherence to a code standard will improve the efficiency of the source code verification activities.
- It can prevent the use of language features that complicate software product verification or introduce potential safety issues. A common example is the deallocation of dynamically allocated objects, which can lead to dangling references if used incorrectly. Verification that a program is not susceptible to such errors would require thorough and complex analysis, and as a result it's typical for a code standard to prohibit deallocation.

GNATcheck provides an extensive set of user-selectable rules to verify compliance with various Ada coding standard requirements. These includes style convention enforcement (casing, indentation, etc.), detection of features that are susceptible to misuse (floating-point equality, `goto` statements), static complexity checks (block nesting, cyclomatic complexity) and detection of features with complex run-time semantics (tasking, dynamic memory).

Since a code standard may include qualitative rules, or rules that are not handled by GNATcheck, verifying that the source code complies with the standard is not always fully automatable. However, there are two ways to extend automated verification:

- GNATcheck's rules are extended on a regular basis in response to customer input, and the tool's enforcement of the new rules is eligible for qualification. Even in the absence of tool qualification, the tool can still save time during verification by detecting rule violations.
- Users can define their own rules as well, in particular using LKQL (LangKit Query Language) for running queries on top of source code.

One issue that comes up with a code standard is how to apply it retrospectively to an existing code base. The first time a compliance checking tool is run, it would not be uncommon to find hundreds or even thousands of deviations. Fixing them all is not only a cumbersome and tedious task, but as a manual activity it's also a potential for introducing new errors into the code. As a result, it is often more practical to focus on those deviations that are directly linked to safety, rather than trying to update the entire application. Then for newly written code the compliance checker can verify that no new deviations are introduced. Deviation identification may be monitored (e.g. with SonarQube or SQUORE) and viewed with AdaCore's GNATdashboard tool. This approach can provide an analysis over time, for example showing the progress of removal of certain categories of deviations that were present in a given baseline.

Another practicality with code standards is that some rules might need to admit deviations in specific contexts when justified (for example the `goto` statement might be acceptable to implement state transitions in code that simulates a finite-state machine, and forbidden elsewhere). GNATcheck allows adding local check exemptions, around a statement or a piece of code. Such exemptions and their justification would then appear in the tool's report.

139.2.6 Checking source code accuracy and consistency with CodeSonar for Ada

	Contributions
Objectives	• Reviews and Analyses of Source Code (A-5[6]: 6.3.4.f)
Activities	• Reviews and Analyses of Source Code (6.3.4)

"Accuracy and consistency" is a rather broad objective in DO - 178C/ED - 12C, identifying a range of development errors that need to be prevented. Satisfying this objective requires a combination of reviews, analyses and tests, and tools may be used for some of these activities. *CodeSonar for Ada* (page 2596) specifically targets issues that correspond to Ada exceptions, such as scalar overflow, range constraint violations, and array indexing errors. It also detects other errors including reads of uninitialized variables, useless assignments, and data corruption due to race conditions. The depth of the tool's analysis can be adjusted based on whether the priority is maximal error detection at the expense of false alarms, or minimal false alarms at the expense of undetected errors.

139.2.7 Checking worst case stack consumption with GNATstack

	Contributions
Objectives	• Reviews and Analyses of Source Code (A-5[6]: 6.3.4.f)
Activities	• Reviews and Analyses of Source Code (6.3.4)

Stack usage is one of the items listed in the "source code accuracy and consistency" objective; i.e., ensuring that the application has sufficient stack memory reserved during program execution. Verification is often achieved by running test cases and measuring the actual stack space used. This approach may provide a false sense of confidence, however, since there is no evidence that the worst case usage has been addressed.

A more precise analysis method is to statically determine the actual stack consumption, looking at the memory statically allocated by the compiler together with the stack usage implied by the subprogram call graphs. The *GNATstack tool* (page 2595) can perform this analysis for Ada and C, determining the maximum amount of memory needed for each task stack.

In many cases, however, not everything can be statically computed; examples are recursive calls, dynamically sized stack frames, and system calls. In such cases, the user can provide a worst-case estimate as input to GNATstack's computation.

139.2.8 Compiling with the GNAT Pro compiler

	Contributions
Objectives	• Integration Process (A-2[7]: 5.4.1.a) • Reviews and Analyses of Integration (A-5[7]: 6.3.5.a)
Activities	• Integration Process (5.4.2.a, 5.4.2.b, 5.4.2.d) • Reviews and Analyses of Integration (6.3.5) • Software Development Environment (4.4.1.f)

The GNAT Pro technology includes GNU gcc-based Ada and C compilation toolsuites in wide use by developers of high assurance software, in particular in a DO - 178C/ED - 12C context. They are available on a broad range of platforms, both native and cross. Embedded targets include various RTOSes for certified applications (such as VxWorks 653, VxWorks 6 Cert,

Lynx178, PikeOS) as well as bare metal configurations, for a wide range of processors (such as PowerPC and ARM).

The Ada language helps reduce the risk of introducing errors during software development (see[630]). This is achieved through a combination of specific programming constructs together with static and dynamic checks. As a result, Ada code standards tend to be shorter and simpler than C code standards, since many issues are taken care of by default. The GNAT Pro compiler and linker provide detailed error and warning diagnostics, making it easy to correct potential problems early in the development process.

As with all AdaCore tools, the list of known problems in the compiler is kept up to date and is available to all subscribers to the technology. A safety analysis of the list entries is also available, helping developers assess potential impact and decide on appropriate actions. Possible actions are code workarounds or a choice of a different set of compiler code generation options.

For certain Ada language features the GNAT Pro compiler may generate object code that is not directly traceable to source code. This non-traceable code can be verified using a traceability analysis (see *Demonstrating traceability of source to object code* (page 2626)).

139.2.9 Using GNATtest for low-level testing

	Contributions
Objectives	• Software Testing (A-6[3,4]: 6.4.c, 6.4.d) • Review and Analyses of Test procedures (A-7[1]: 6.4.5.b) and results (A-7[2]: 6.4.5.c)
Activities	• Normal Range Test Cases (6.4.2.1) • Robustness Test Cases (6.4.2.2) • Review and Analyses of Test procedures and results (6.4.5) • Software Verification Process Traceability (6.5.b, 6.5.c)

The software architecture is developed during the design process, identifying components and sometimes subcomponents. The behavior of each terminal component is defined through a set of low-level requirements. Typically, low-level testing consists in

1. Developing test cases from the low-level requirements,
2. Implementing the test cases into test procedures,
3. Exercising the test procedures separately on one or more components, and
4. Verifying the test results

GNATtest (page 2597) may be used to develop the test data. The general approach is for GNATtest to generate an Ada test harness around the component under test, leaving the tester to complete test skeletons based on the predefined test cases, with actual inputs and expected results. Since the test generation is carried out in a systematic way, it's very easy to identify where tests are missing (they will be reported as non-implemented).

The tool works iteratively. If it's called a second time on a set of files that have changed, it will identify the changes automatically, preserving existing tests and generating new tests for newly added subprograms.

A component under test may call external components. One possible approach is to integrate the components incrementally. This has the benefit of preserving the actual calls, but it may be difficult to accurately manage the component interfaces. Another approach is to replace some of the called subprograms with dummy versions (stubs). GNATtest supports both approaches, and can generate stub skeletons if needed.

[630] Paul E. Black, Michael Kass, Michael Koo, and Elizabeth Fong. *Source Code Security Analysis Tool Functional Specification*. National Institute for Standards and Technology (NIST), 2011.

The functionality just described is common to most test tools. A novel and useful feature of GNATtest is its ability to develop the test cases during the design process. (Note that independence between design and test cases is not required. Independence is required between code development and test case derivation, to satisfy the independence criteria of objectives A6-3 and 4 for software level A and B).

Approach 1: Test cases are not specified in Ada specifications

A traditional approach can be followed by GNATtest — that is to say, test cases are described outside of the Ada specification, but linked to a particular function. When working this way, GNATtest will generate one test per subprogram; for example :

```
function Sqrt (X : Float) return Float;
```

This will generate one unique test procedure skeleton.

Approach 2: Test cases are developed during the design process

In this approach, Ada package specifications are considered as an output of the design process (see *Using Ada during the design process* (page 2607)). More than one test per subprogram may be developed. Here's a simple example:

```
function Sqrt (X : Float) return Float
 with Pre       =>  X >= 0.0,
      Post      =>  Sqrt'Result >= 0.0,
      Test_Case =>
        (Name     => "test case 1",
         Mode     => Nominal,
         Requires => X = 16.0,
         Ensures  => Sqrt'Result = 4.0),
      Test_Case =>
        (Name     => "test case 2",
         Mode     => Robustness,
         Requires => X < 0.0,
         Ensures  => raise Constraint_Error
                     with "Non-negative value needed");
```

As part of the specification for the Sqrt function, the GNAT-specific aspect `Test_Case` is used to define two test cases. The one named "test case 1" is identified as `Nominal`, which means that the argument supplied as *Requires* should satisfy the function's precondition, and the argument supplied as `Ensures` should satisfy the function's postcondition. The test case named "test case 2" is specified as `Robustness`, so the pre- and postconditions are ignored. As with all test cases, these are based on the function's requirements.

When generating the test harness, GNATtest provides a skeleton of the test procedures, and the user has to plug in the input values (from the `Requires` argument) and the expected results (from the `Ensures` argument) for all test cases defined in the Ada package specification.

GNATtest will insert specific checks to verify that, within "test case 1", all calls made to `Sqrt` have X equal to `16.0`, and each value returned is equal to 4.0. This not only verifies that the test succeeded, but also confirms that the test conducted is indeed the intended test. As a result, GNATtest verifies that the test procedures comply with the test cases, that they are complete (all test cases have been implemented and exercised), and that the test results are as expected.

In addition, the traceability between test case, test procedures and test results is direct, and does not require production of further trace data.

Approach 3: Test cases are developed separately from the design process

The two test cases developed in Approach 2 are not sufficient to fully verify the `Sqrt` function. To comply with DO - 178C/ED - 12C Table A-6 Objectives 3 and 4, the activities presented in §6.4.2 (Requirements-Based Test Selection) for normal and robustness cases are applicable. It is not generally practical to include all the test cases in the Ada package specification.

Another consideration is the criterion of independence between code and test case development. Thus Approach 2 is applicable only if the Ada package specification is developed during the design process (and not during the coding process).

An alternative approach is to develop the test data separately from the Ada package specifications, while some test cases (effectively test case *classes*) are still defined and used by GNATtest to develop the test harness. Here's an example:

```
function Sqrt (X : Float) return Float
with Test_Case =>
       (Name     => "test case 1",
        Mode     => Nominal,
        Requires => X > 0.0,
        Ensures  => Sqrt'Result > 0.0),
     Test_Case =>
       (Name     => "test case 2",
        Mode     => Nominal,
        Requires => X = 0.0,
        Ensures  => Sqrt'Result = 0.0),
     Test_Case =>
       (Name     => "test case 3",
        Mode     => Robustness,
        Requires => X < 0.0,
        Ensures  => raise Constraint_Error
                    with "Non-negative value needed");
```

In this approach, three `Test_Case` aspects are defined — in effect test case classes that partition the set of possible input values — defining the expected high-level characteristics of the function. For each `Test_Case`, at least one actual test case will be developed. In this example, at least three test cases need to be defined, corresponding to an actual parameter that is positive, zero, or negative, with the respective expected results of positive, zero, and raising an exception.

As in Approach 2, the skeleton generated by GNATtest must be completed by the user, but in that case the data produced are the actual test cases (and cannot be considered as test procedures). For example, based on the range of the input, the user should define tests for boundary values, for the value 1, or any representative data (equivalence classes).

As previously, GNATtest will insert specific checks based on the `Requires` and `Ensures` values for each `Test_Case`. Then GNATtest will verify that at least one actual test case has been implemented for each `Test_Case`, and that the results are correct.

Note that in this approach, the test procedures become the internal files generated by GNATtest. Therefore, as it will be difficult to verify the correctness of these files, GNATtest qualification is needed in order to satisfy objective A7-1 "test procedures are correct".

139.2.10 Using GNATemulator for low-level and software / software integration tests

	Contributions
Objectives	• Software testing (A-6[1,2,3,4]: 6.4.a, 6.4.b, 6.4.c, 6.4.d)
Activities	• Test environment (6.4.1) • Software Integration testing (6.4.3.b) • Low Level testing (6.4.3.c)

As stated in DO - 178C/ED - 12C §6.4.1:

> "More than one test environment may be needed to satisfy the objectives for software testing.... Certification credit may be given for testing done using a target computer emulator or a host computer simulator".

But an integrated target computer environment is still necessary to satisfy the verification objective (A6-5) that the executable object code is compatible with the target computer. These tests, referred to as "Hardware / Software integration tests", are necessary since some errors might only be detected in this environment. As stated in DO - 330/ED - 215, FAQ D.3, qualification of a target emulator or simulator may be required if they are used to execute the Hardware / Software integration tests.

Although GNATemulator might thus not be applicable in the scope of Hardware / Software integration tests, it is allowed for all other tests (see DO - 330/ED - 215 FAQ D.3). Two approaches may be used:

- To perform some tests (that may be part of low-level testing and/or Software / Software integration testing) on GNATemulator, and to claim credit on this environment for satisfying the objectives concerning the Executable Object Code's compliance with its requirements
- To use GNATemulator to prototype and gain confidence in tests prior to re-running the tests on the actual target computer environment.

In any event GNATemulator helps considerably in the early detection of errors in both the software and the test procedures. GNATemulator works in much the same fashion as a "Just In Time" (JIT) compiler: it analyzes the target instructions as it encounters them and translates them on the fly (if not done previously) into host instructions, for example an x86. This makes it particularly suitable for low-level testing, at least for those tests that do not depend on actual timing on the target.

GNATemulator also provides an easy way to interact with emulated devices and drivers on the host. Reads and writes to emulated memory can trigger interactions with such code, through the GNATbus interface.

139.2.11 Structural code coverage with GNATcoverage

	Contributions
Objectives	• Test Coverage Analysis (A-7[5]: 6.4.4.c)
Activities	• Structural Coverage Analysis (6.4.4.2.a, 6.4.4.2.b)

The structural coverage analysis objectives of DO - 178C/ED - 12C serve to verify the thoroughness of the requirements-based tests and to help detect unintended functionality. The scope of this analysis depends on the software Level:

- Statement coverage for Level C,
- Statement and Decision coverage for level B, and
- Statement, Decision and Modified Condition / Decision Coverage (MC/DC) at level A.

These three criteria will be explained through a simple (and artificial) example, to determine whether a command should be issued to open the aircraft doors:

```
Closed_Doors               : Integer;
Open_Ordered, Plane_Landed : Boolean;
 ...

if Closed_Doors > 0 and then Open_Ordered and then Plane_Landed then
   Open_Doors;
end if;
```

Note: the Ada short-circuit form **and then** is equivalent to the C shortcut boolean operator &&: the second operand is evaluated if and only if the first operand evaluates to **True**. If the first operand evaluates to **False**, then the expression's value is **False**.

This code fragment consists of two statements:

- The enclosing **if** statement
- The enclosed `Open_Doors;` statement, which will be executed if the decision in the **if** statement is **True**

The **if** statement in turn contains a single decision:

```
Closed_Doors > 0 and then Open_Ordered and then Plane_Landed
```

and this decision contains three conditions:

- `Closed_Doors > 0`
- `Open_Ordered`
- `Plane_Landed`

At the statement level, both statements need to be executed during requirements-based tests. This criterion may be achieved with only one test, with all three conditions **True**.

It's important to realize that this piece of code is the implementation of one or several requirements, and a single test with all three conditions **True** will almost certainly fail to satisfy the requirement coverage criterion. Further, this single test is probably not sufficient to detect implementation errors: the purpose of testing is to detect errors and to show that the software satisfies its requirements, not to achieve structural code coverage. Structural coverage analysis is mainly a test completeness activity.

At the decision level, each decision must be exercised both with a **True** and **False** outcome. In the example above, this may be achieved with only two tests; one test with all three conditions **True**, and a second test with at least one **False**.

The third level is called MC/DC, for Modified Condition / Decision Coverage. The goal is to assess that each condition within a decision has an impact, independently of other conditions, on the decision outcome.

The motivation for MC/DC is most easily appreciated if we first look at what would be required for full coverage of each possible combination of truth values for the constituent conditions. This would require eight tests, represented in the following table:

Closed_Doors > 0	Open_Ordered	Plane_Landed	Result
True	True	True	True
True	True	False	False
True	False	True	False
True	False	False	False
False	True	True	False
False	True	False	False
False	False	True	False
False	False	False	False

In the general case, 2^n cases would be needed for a decision with n conditions, and this would be impractical for all but small values of n. The MC/DC criterion is achieved by selecting combinations demonstrating that each condition contributes to the outcome of the decision.

With MC/DC, each condition in the decision must be exercised with both `True` and `False` values, and each condition must be shown to independently affect the result. That is, each condition must be exercised by two tests, one with that condition `True` and the other with the condition `False`, such that:

- The result of the decision is different in the two tests, and
- For each other condition, the condition is either `True` in both tests or `False` in both tests

Here the MC/DC criterion may be achieved with four tests: one test with all three conditions `True`, and each other test changing the value of one condition to `False`:

	Closed_Doors > 0	Open_Ordered	Plane_Landed	Result
Baseline	True	True	True	True
Test 1	False	True	True	False
Test 2	True	False	True	False
Test 3	True	True	False	False

Each condition thus has two associated tests, the one marked as baseline, and the one with `False` in that condition's column. These two tests show how that condition independently affects the outcome: The given condition is `True` in the baseline and `False` in the other, each other condition has the same value in both tests, and the outcome of the two tests is different.

In the general case, the MC/DC criterion for a decision with n conditions requires n+1 tests, instead of 2^n. For more information about MC/DC, see[631].

GNATcoverage provides output that helps comply with DO - 178C/ED - 12C objectives for test coverage of software structure (Table 7, objectives 5, 6, and 7), for both Ada and C source code. The tool computes its results from trace files that show which program constructs have been exercised by a given test campaign. With source code instrumentation, the tool produces these files by executing an alternative version of the program, built from source code instrumented to populate coverage-related data structures. Through an option to GNATcoverage, the user can specify the granularity of the analysis by choosing any of the coverage criteria defined in DO - 178C/ED - 12C: Statement Coverage, Decision Coverage, or Modified Condition / Decision Coverage (MC/DC).

Source-based instrumentation brings several major benefits: efficiency of tool execution (much faster than alternative coverage strategies using binary traces and target emulation,

[631] Kelly J. Hayhurst, Dan S. Veerhusen, John J. Chilenski, and Leanna K. Rierson. *A Practical Tutorial on Modified Condition / Decision Coverage*. NASA, 2001. URL: https://shemesh.larc.nasa.gov/fm/papers/Hayhurst-2001-tm210876-MCDC.pdf.

especially on native platforms), compact-size source trace files independent of execution duration, and support for coverage of shared libraries.

139.2.12 Data and control coupling coverage with GNATcoverage

	Contributions
Objectives	• Test Coverage Analysis (A-7[8]: 6.4.4.d)
Activities	• Structural Coverage Analysis (6.4.4.2.c)

DO - 178C/ED - 12C objective A7-8 states:

> "Test coverage of software structure (data coupling and control coupling) is achieved".

This is part of overall structural coverage analysis. Although structural coverage activities (Statement, Decision, or MC/DC) can be carried out at various times, it is often performed during low-level testing. This allows precise control and monitoring of test inputs and code execution. If code coverage data is retrieved during low-level testing, structural coverage analysis can assess the completeness of the low-level tests.

In addition, the completeness of the integration tests needs to be verified. For that purpose the integration tests have to be shown to exercise the interactions between components that are otherwise tested independently. This is done through data and control coupling coverage activities. Each data and control coupling relationship must be exercised at least once during integration tests.

Data and control coupling are the interfaces between components, as defined in the architecture. More specifically, data coupling concerns the data objects that are passed between modules. These may be global variables, subprogram parameters, or any other data passing mechanisms. Control coupling concerns the influence on control flow. Inter-module subprogram calls are obvious cases of control coupling (they initiate a control flow sequence) but subtler cases such as a global variable influencing a condition can be also considered as control coupling. For example, if module `Alpha` has something like:

```
if G then
   Do_Something;
else
   Do_Something_Else;
end if;
```

and in a module `Beta`:

```
G := False;
```

Then this is really an example of control coupling, and not data coupling. Using a global variable to effect this control flow is considered an implementation choice.

In the software engineering literature, the term *coupling* generally has negative connotations since high coupling can interfere with a module's maintainability and reusability. In DO - 178C/ED - 12C there is no such negative connotation; coupling simply indicates a relationship between two modules. That relationship needs to be defined in the software architecture and verified by requirements-based integration tests.

One strategy to verify coverage of data and control coupling is to perform statement coverage analysis during integration testing. GNATcoverage may be used in this way to detect incomplete execution of such data and control flows. This may require coding constraints, such as limited use of global data, or additional verification for such data:

- Parameter passing and subprogram calls: Statement coverage ensures that all subprograms are called at least once. Additional verification is needed to demonstrate correctness properties for the parameters.
- Global data: The `Global` aspect in SPARK (and in Ada 2022) can be used to verify correct usages of global data.

139.2.13 Demonstrating traceability of source to object code

	Contributions
Objectives	• Test Coverage Analysis (A-7[5]: 6.4.4.c)
Activities	• Structural Coverage Analysis (6.4.4.2.b)

For software at level A, DO - 178C/ED - 12C objective A7-9 requires identifying if code not visible at the source code level is added by the compiler, linker, or other means; if so, it is necessary to verify such code for correctness. Compiler-added code typically takes the form of extra branches or loops that are explicit in the object code but not at the source level. One example in Ada is the implicit checking that is often required by the language semantics.

A statement like:

```
A : Integer range 1..10;
B : Integer;
...
A := B;
```

may be compiled into the following pseudo-object code:

```
if B >= 1 or else B <= 10 then
   A := B;
else
   raise Constraint_Error;
end if;
```

This assumes that checks are retained at run-time. However, even with checks disabled, a compiler for either Ada or C may still need to generate non-traceable code to implement some language constructs. An Ada example is array slice assignment, which results in loops at the object code level on typical target hardware:

```
A, B : String (1..100);
...
A (1..50) := B (11..60);
```

AdaCore has verified the correctness of non-traceable code for the *GNAT Pro for Ada* and *GNAT Pro for C* compilers, based on representative samples of source code. Samples were chosen for the language features permitted by common code standards. Object code was generated for each sample, and any additional (non-traceable) code was identified. For each non-traceable feature, additional requirements and tests were provided to verify that the behavior of the resulting code was indeed as required.

Traceability analyses for *GNAT Pro for Ada* and *GNAT Pro for C* are available. These analyses take into account the specific compiler version, compiler options, and code standard that are used, to ensure that the code samples chosen are representative. If some specific language features, options, or compiler versions are not suitable for the analysis, appropriate adaptations are made.

139.3 Use case #1b: Coding with Ada using OOT features

This use case is based on use case #1, taking advantage of Ada and the AdaCore ecosystem, but with a design that uses Object-Oriented Technologies. As a result, the following *vulnerabilities* identified in the technology supplement DO - 332/ED - 217 need to be addressed:

- Local type consistency
- Dynamic memory management
- Parametric polymorphism (genericity)
- Overloading
- Type conversion
- Exception management
- Component-based development

139.3.1 Object orientation for the architecture

	Contributions
Objectives	• Software Design Process Objectives (A-2[4]: 5.2.1.a)
Activities	• Software Design Process Activities (OO.5.2.2.h) • Software Development Process Traceability (OO.5.5.d)
Vulnerabilities	• Traceability (OO.D.2.1)

Object orientation is a design methodology, a way to compose a system where the focus is on the kinds of entities that the system deals with, and their interrelationships. Choosing an object-oriented design will thus have a significant impact on the architecture, which is expressed in terms of classes and their methods (or primitive operations in Ada). This architecture can be modeled in many ways, for example with UML class diagrams.

The use of OOT can affect traceability between low-level requirements and code. Without object orientation, traceability is generally between a set of requirements and one module, one function or one piece of code. In an object-oriented design, as defined in DO - 332/ED - 217, §O.O.5.5:

> "All functionality is implemented in methods; therefore, traceability is from requirements to the methods and attributes that implement the requirements".

139.3.2 Coverage in the case of generics

	Contributions
Objectives	• Test Coverage Analysis (A-7[4,5]: 6.4.4.b, 6.4.4.c)
Activities	• Requirement coverage analysis (6.4.4.1) • Structural Coverage Analysis (6.4.4.2.a, 6.4.4.2.b)
Vulnerabilities	• Parametric Polymorphism (OO.D.1.2) • Structural Coverage (OO.D.2.2)

Genericity is one of the *related techniques* (not part of OOT) that is covered by DO - 332/ED - 217. A generic unit is a template for a piece of code that can be instantiated with different parameters, including types and subprograms. A complication with respect to certification

is that the same generic unit may have different instantiations that behave differently. Consider, for example, a simple generic Ada function that can be instantiated with an integer type to perform some basic computation:

```
generic
   type Int_Type is range <>;
function Add_Saturated (Left, Right, Max : Int_Type)
  return Int_Type
  with Pre => Max>0;
function Add_Saturated (Left, Right, Max : Int_Type)
   return Int_Type is
   Temp : Int_Type;
begin
   Temp := Left + Right;

   if Temp > Max then
      return Max;
   elsif Temp < -Max then
      return -Max;
   else
      return Temp;
   end if;
end Add_Saturated;
```

Then consider two separate instantiations:

```
with Add_Saturated;
procedure Test_Gen is
   function Add_1 is new Add_Saturated (Integer);

   type Small_Int is range -10 .. 10;
   function Add_2 is new Add_Saturated (Small_Int);

   N1 : Integer;
   N2 : Small_Int;
begin
   N1 := Add_1 (6, 6, 10); -- Correctly yields 10
   N2 := Add_2 (6, 6, 10); -- Raises Constraint_Error
end Test_Gen;
```

Calling `Add_1 (6, 6, 10)` will yield 10 as a result. Calling `Add_2 (6, 6, 10)` will raise `Constraint_Error` on the first addition, since the sum `Left + Right` will be equal to 12 and therefore violate the range constraint for `Small_Int`.

Different instantiations of the same generic unit can thus exhibit different behaviors. As a result, DO - 332/ED - 217 specifies that each generic instance must be tested (and covered); see section OO.D.1.2.3.

GNATtest will generate a test harness taking this requirement into account. In particular, it will generate a separate testing setup for each instance, while keeping a generic test procedure for all of them.

GNATcoverage can separately report the coverage of each generic instance, based on the `-S instance` switch.

With respect to traceability, the code of a generic instantiation is traceable to the source. Indeed, at the point of instantiation, the effect is as though the generic template were expanded in place, with formal parameters replaced by the actuals. (This expansion is not at the level of source text, but rather is based on a program representation where all names have been semantically resolved.) As a result, using a generic doesn't add any non-traceable code. Code is traced from the generic template to the object code, once per instance.

139.3.3 Dealing with dynamic dispatching and substitutability

	Contributions
Objectives	• Software Design Process Objectives (A-2[4]: 5.2.1.a) • Local Type Consistency Verification Objective (OO.A-7[OO 10]: OO.6.7.1)
Activities	• Software Design Process Activities (OO.5.2.2.i) • Local Type Consistency Verification Activity (OO.6.7.2)
Vulnerabilities	• Inheritance (OO.D.1.1)

One of the major features of OOT is dynamic dispatching (also called *dynamic binding*), which adds considerable expressive power but also presents challenges to verification. With dynamic dispatching, the subprogram to be invoked on a reference to a target object is not known statically but rather is resolved at run time based on which class the target object belongs to. This differs from a call through an access-to-subprogram value in the sense that, with dynamic dispatching, the potential destination subprograms are constrained to a specific class hierarchy as determined by the type of the reference to the target object (the *controlling parameter*, in Ada terms).

In Ada, a subprogram that can be invoked through dynamic dispatching — this is known as a *primitive subprogram* — can never be removed by a subclass; it is either inherited or overridden. Thus on a call that is dynamically dispatched, although it is not known at compile time which subclass's version of the subprogram will be invoked, some subclass's implementation of the subprogram will indeed be called. Ada is not susceptible to "no such method" errors that can arise with dynamic dispatching in some other languages.

Understanding Substitutability

From a safety point of view, not knowing the specific target of a given call introduces significant issues for verifiability. DO - 332/ED - 217 states that if an inheritance hierarchy is constructed so that each subclass specializes its superclass (i.e., wherever a superclass instance is permitted a subclass instance may be substituted) then dynamic dispatching is acceptable. This substitutability property for a class inheritance hierarchy is known as the *Liskov Substitution Principle* (LSP).

If a hierarchy complies with LSP, then testing and other verification can be conducted based on properties defined at the class level, which will then need to be respected by each subclass. As will be explained below, this has implications on the pre- and postconditions that are allowed when a dispatching subprogram is overridden.

Here is a specific — although simplified — example: an aircraft type with a subprogram that is supposed to open the doors.

```
package Aircraft_Pkg is
   type Aircraft is abstract tagged private;

   procedure Open_Doors (Self : Aircraft)
   with Pre'Class  => Self.On_Ground,
        Post'Class => Self.Doors_Opened;

   ...
private
   ...
end Aircraft_Pkg;
```

The contracts for the pre- and postconditions reflect the low-level requirements:

- the aircraft has to be on the ground prior to having its doors opened, and
- the doors are opened as a result of the call.

The Aircraft type could be used as follows:

```
procedure Landing_Procedure (My_Aircraft : Aircraft'Class) is
begin
   ...
   while not My_Aircraft.On_Ground loop
      ...
   end loop;

   -- Here if My_Aircraft is on the ground

   My_Aircraft.Open_Doors;  -- Dispatching call
   My_Aircraft.Let_Passengers_Out;
   ...
end Landing_Procedure;
```

We're first waiting until the aircraft is actually on the ground, then open the doors, then as the doors are opened we let passengers out.

All types in the Aircraft inheritance hierarchy have to comply with the Aircraft contracts. That is, for any type in the Aircraft'Class hierarchy, the Open_Doors subprogram for that type can require at most the On_Ground precondition and nothing stronger. If a stronger precondition were imposed, then a dynamically dispatching call of Open_Doors could fail if the actual parameter were of this (non-substitutable) type. The extra precondition would not necessarily be known to clients of the root type Aircraft.

Analogously for the postcondition, any type in the Aircraft'Class hierarchy has to guarantee *at least* the Doors_Opened property, since this will be assumed by callers of Open_Doors.

In short, the substitutability property can be summarized as follows:

> If a type hierarchy is to be substitutable, then a dispatching subprogram for a derived type can weaken but not strengthen the precondition of the overridden subprogram for its parent type, and can strengthen but not weaken the postcondition.

The class-wide Pre'Class and Post'Class aspects are inherited (unless overridden) and have other semantics that directly support this substitutability property. The specific (non-class-wide) aspects Pre and Post are not inherited and should only be used if the hierarchy does not support substitutability.

Let's now define a Jet:

```
type Jet is new Aircraft with ...

overriding
procedure Open_Doors (Self : Jet)
with Pre        => Self.On_Ground and Self.Engines_Off,
     Post'Class => Self.Doors_Opened and not Self.Pressurized;
```

Suppose that Landing_Procedure is invoked on an object of type Jet:

```
J : Aircraft'Class := Jet'(...);
...
Landing_Procedure (J);
```

In the call My_Aircraft.Open_Doors, first the precondition for Open_Doors for Aircraft will be evaluated (since the actual parameter is of the class-wide type Aircraft'Class. That's not a problem, since the caller sees this precondition. However, then the specific precondition for Open_Doors for Jet is evaluated, and there is a problem with the additional constraint — requiring the engines to be off. The Jet type could have been defined long after the Landing_Procedure subprogram was written, so the design of the Landing_Procedure code would not have taken the added precondition into account. As a result, the Open_Doors procedure could be invoked when the engines were still running, violating

the requirement. (With run-time assertion checking enabled, an exception would be raised.) The type Jet is not substitutable for the type Aircraft on invocations of Open_Doors.

The non-substitutability is reflected in the use of the specific aspect Pre rather than the class-wide aspect Pre'Class. In a type hierarchy rooted at type T where Pre'Class is specified at each level for a subprogram Proc, the effective precondition for a dispatching call X.Proc where X is of the type T'Class is simply the precondition specified for Proc for the root type T (which is the only precondition known to the caller). In the Jet example, if Pre'Class had been used, a dispatching call to Open_Doors would not check the Engines_Off condition.

In short, if a subclass is to be substitutable then it may weaken but not strengthen a subprogram's precondition, and it should use Pre'Class rather than Pre. If a subclass needs to strengthen a precondition then it is not substitutable and should use Pre rather than Pre'Class.

The postcondition for Open_Doors for Jet does not have this problem. It adds an additional guarantee: pressurization is off after the opening of the doors. That's OK; it doesn't contradict the expectations of the Landing_Procedure subprogram, it just adds an additional guarantee.

The Jet type illustrated non-substitutability due to precondition strengthening. Non-substitutability can also arise for postconditions, as illustrated in a slight variation of the Aircraft type:

```
package Aircraft_Pkg is
   type Aircraft is abstract tagged private;

   procedure Open_Doors (Self : Aircraft)
   with Pre'Class  => Self.On_Ground,
        Post       => Self.Doors_Opened;
        -- Specific, not class-wide

   ...
private
   ...
end Aircraft_Pkg;
```

Here's a possible declaration for a hot air balloon:

```
type Hot_Air_Balloon is new Aircraft with ...

overriding
procedure Open_Doors (Self  : Hot_Air_Balloon)
with Pre'Class  => Self.On_Ground or Self.Tethered,
     Post       => Self.Doors_Unlocked;
```

In this case, the precondition is relaxed (we're assuming a short tether). This is acceptable, since the landing procedure will still check the stronger precondition and wait for the aircraft to be on the ground; the class-wide precondition of the root type is checked on a dispatching call. (The weaker precondition would be checked on a call such as B.Open_Doors where B is either of the specific type Hot_Air_Balloon or the class-wide type Hot_Air_Balloon'Class.)

However, a Hot_Air_Balloon is less automated than a Jet: the doors don't open automatically, they just unlock. The Landing_Procedure subprogram assumes the postcondition for Aircraft (that the doors are opened), but this is not guaranteed for a Hot_Air_Balloon, so passengers might be pushed out while the doors are unlocked but still closed. The new postcondition is breaking the requirement by weakening its parent type's postcondition, and this is not acceptable. Thus the Hot_Air_Balloon type is not substitutable for Aircraft.

Substitutability defects may be evidence of a number of problems; for example, the hierar-

chy of classes or requirements may be incorrect, or the classes may be modeling properties inappropriately. Overall, this indicates design issues to be addressed when specifying the low-level requirements and/or architecture.

A natural question is how to detect substitutability defects (or achieve confidence that such defects are not present) in the application. DO - 332/ED - 217 provides three approaches: pessimistic testing, local substitution tests, or formal proofs.

Verifying substitutability by pessimistic testing

Pessimistic testing is conceptually the easiest to understand. The idea is to test at each point of dispatch all possible types that could be substituted. In the `Landing_Procedure` example, assuming that our system is managing both jets and hot air balloons, this would mean two sets of tests: one for the Jet type, and one for Hot_Air_Balloon. This is working around the difficulty of not knowing statically the potential target of a call: we just test all possible scenarios.

This is particularly appropriate with *flat* hierarchies, which may be broad but not deep. An example is an OOP design pattern for an abstract root type (such as a container data structure) with concrete specializations corresponding to different representational choices. In this case, regular requirement-based testing is equivalent to pessimistic testing. However, the complexity of additional testing can quickly become unmanageable as the depth of the class hierarchy increases.

Verifying substitutability through requirement-based testing

In this case verification of substitutability is done on top of regular testing. In the above examples the `Aircraft`, `Jet` and `Hot_Air_Balloon` requirements are all associated with specific requirement-based tests. Substitutability can be demonstrated by running top level tests with instances of other types of the class. In other words, tests developed based on requirements of `Aircraft` must pass with instances of `Jet` and `Hot_Air_Balloon`. This is enough to demonstrate substitutability, effectively testing the substitution. This may require more or fewer tests depending on OOP usage. In particular, for large class hierarchies, testing at the class level is much more cost-effective than testing every possible target of every possible dispatching call in the actual code.

The GNATtest tool supports generation of the appropriate test framework for substitution testing; see the GNATtest option `--validate-type-extensions`.

Verifying substitutability through formal proof

In conjunction with DO - 333/ED - 216 (Formal Methods supplement), and assuming that requirements can be expressed in the form of pre- and postconditions, the consistency between an overriding subprogram and its parent type's version can be verified through formal proof. This can be done in particular with the SPARK language. There are two criteria for substitutability:

- The precondition of a subprogram for a type must imply the precondition of each overriding subprogram in the class hierarchy.
- The postcondition of any overriding subprogram for a type must imply the postcondition of the corresponding subprogram for each ancestor type in the hierarchy

These preconditions and postconditions — or requirements — must also be verified, through either requirement-based testing or formal proofs.

The SPARK GNATprove tool can verify consistency of classes of types, and in particular consistency of pre- and postconditions as described above. To enable such verification, these must be declared as class-wide contracts as in the initial example of the *Aircraft* type above.

Differences between local and global substitutability

DO - 332/ED - 217 does not require classes to be globally substitutable, but only locally; that is, only around actual dispatching points. For example, the following code is not globally substitutable, but is locally substitutable at the dispatching calls:

```
package Aircraft_Pkg is
   type Aircraft is abstract tagged private;

   procedure Open_Doors (Self : Aircraft)
   with Pre'Class  => Self.On_Ground,
        Post'Class => Self.Doors_Opened;

   procedure Take_Off (Self : Aircraft)
   with Pre'Class  => Self.On_Ground and not
                      Self.Doors_Opened,
        Post'Class => not Self.On_Ground;
   ...
private
   ...
end Aircraft_Pkg;

package Aircraft_Pkg.Jet_Pkg is
   type Jet is new Aircraft with ...

   overriding
   procedure Open_Doors (Self : Jet)
   with Pre        => Self.On_Ground and Self.Engines_Off,
                      -- Not substitutable
        Post'Class => not Self.Pressurized;

   overriding
   procedure Take_Off (Self : Aircraft)
   -- Inherit Aircraft's precondition
   with Post'Class => not Self.On_Ground and
                      Self.Speed >= 100.0;

   ...
private
   ...
end Aircraft_Pkg.Jet_Pkg;
...
X, Y : Aircraft'Class := Jet'(...)
...

X.Take_Off;
Y.Take_Off;
```

The `Jet` type is not globally substitutable for `Aircraft`, since the precondition on `Open_Doors` for `Jet` is stronger than the precondition on `Open_Doors` for `Aircraft`. But `Jet` is locally substitutable in the above fragment:

- The invocations `X.Take_Off` and `Y.Take_Off` dispatch to `Jet`, but `Jet` is substitutable for `Aircraft` here:
  - The precondition for `Take_Off(Aircraft)` is inherited by `Jet`,and
  - The postcondition for `Take_Off(Aircraft)` is strengthened by `Jet`

Whether it is easier to demonstrate local versus global substitutability for a given class depends on the architecture and the ease of identification of actual dispatch destinations and substitutability. DO - 332/ED - 217 allows the applicant to decide on whichever means is the most appropriate.

139.3.4 Dispatching as a new module coupling mechanism

	Contributions
Objectives	• Test Coverage Analysis (A-7[8]: 6.4.4.d)
Activities	• Structural Coverage Analysis (6.4.4.2.c)
Vulnerabilities	• Structural Coverage (OO.D.2.2)

With procedural programming, modules can be interfaced, or coupled, through parameter passing, subprogram calls or global variables (data and control coupling). Object orientation introduces a new way in which two modules may interface with each other: by extension / type derivation. Following-up on previous examples:

```
procedure Control_Flight (Plane : Aircraft'Class) is
begin

   ...

   -- Dispatching call, may call Take_Off from instances
   -- defined in other modules, creating coupling
   -- relationship with those modules
   Plane.Take_Off;

  ...

end Control_Flight;
```

Aircraft of different types may be defined in separate modules. A connection between these modules and the rest of the application may be made by dispatching from this call. All objectives that apply to control and data coupling now apply to type derivation coupling, in particular the coverage objectives. Whether or not testing with all possible derivations in the system is used (i.e., pessimistic testing) depends on the strategy chosen for substitutability demonstration.

139.3.5 Memory management issues

	Contributions
Objectives	• Software Design Process Objectives (A-2[3,4]: 5.2.1.a) • Reviews and Analyses of Software Architecture (OO.A-4[8]: OO.6.3.3.a) • Dynamic Memory Management Verification Objective (OO.A-7[OO10]: OO.6.8.1)
Activities	• Software Design Process Activities (OO.5.2.2.j) • Dynamic Memory Management Verification Activities (OO.6.8.2) • Reviews and Analyses of Software Architecture (OO.6.3.3)
Vulnerabilities	• Dynamic Memory Management (OO.D.1.6)

In addition to local type consistency, which was described in the preceding section, DO - 332/ED - 217 also introduced another new verification objective: *robustness of dynamic memory management*. This objective encompasses not only explicit use of dynamic memory, through either automatic reclamation (*garbage collection*) or application-provided allocation / deallocation, but also implicit uses through higher level data structures such as object collections of various kinds. DO - 332/ED - 217 identifies a number of criteria that need to be met by any memory management scheme:

- The allocator returns a reference to a valid piece of memory, not otherwise in use

- If enough space is available, allocations will not fail due to memory fragmentation
- An allocation cannot fail because of insufficient reclamation of inaccessible memory
- The total amount of memory needed by the application is available (that is, the application will not fail because of insufficient memory)
- An object is only deallocated after it is no longer used
- If the memory management system moves objects to avoid fragmentation, inconsistent references are prevented
- Allocations and deallocations complete in bounded time

Meeting these criteria may be the responsibility of the run-time memory management library (referred to as the "memory management infrastructure", or MMI in DO - 332/ED - 217) or the application code (AC). Table OO.D.1.6.3 in DO - 332/ED - 217 presents several different memory management techniques that can be used. For each technique the table identifies whether the MMI or the AC is responsible for meeting each criterion.

Dynamic memory is identified as a specific issue in object orientation because, in many languages, it is very difficult or even impossible to use object-oriented paradigms without dynamic memory management. This is in particularly true for reference-based languages such as Java.

Although dynamic memory is also helpful when OOP is used in Ada, simple architectures may allow creating (and subsequently dispatching on) stack-resident or library-level objects, without needing dynamic memory. This can be done if such objects are of a class-wide type. The main constraint is that each object has to be initialized at declaration, and its specific type cannot change later. For example, the following code provides a function returning an object of a type in the `Aircraft` class hierarchy, depending on a parameter:

```
type Aircraft        is abstract tagged ...
type Jet             is new Aircraft with ...
type Hot_Air_Balloon is new Aircraft with ...
...
function Create (T : Integer) return Aircraft'Class is
begin
   if T = 1 then
      return Jet'(<initialization of a Jet>);
   elsif T = 2 then
      return Hot_Air_Balloon'(...);
       -- initialization of a Hot_Air_Balloon
   else
      raise <some exception>;
   end if;
end Create;
```

Objects of the class-wide type `Aircraft'Class` can be created as local or global variables:

```
N : Integer        := Get_Integer;  -- Dynamically computed
P : Aircraft'Class := Create (N);
...
P.Take_Off;
```

Here, P is allocated on the stack and may be either a `Jet` or a `Hot_Air_Balloon`. The call to `P.Take_Off` will dispatch accordingly.

For notational convenience it may be useful to reference objects of a class-wide type through access values (pointers), since that makes it easier to compose data structures, but to prevent dynamic allocation. This can be achieved in Ada:

```
type Aircraft        is abstract tagged ...
type Jet             is new Aircraft with ...
```

(continues on next page)

(continued from previous page)

```
type Hot_Air_Balloon is new Aircraft with ...

type Aircraft_Ref is access all Aircraft'Class;
for Aircraft_Ref'Storage_Size use 0;
   -- No dynamic allocations
...
Jet_1, Jet_2                    : aliased Jet := ...;
Balloon_1, Balloon_2, Balloon_3 : aliased Hot_Air_Balloon := ...;

type Aircraft_Pool_Type is array(Positive range <>) of Aircraft_Ref;
Pool : Aircraft_Pool_Type := (Jet_2'Access,
                              Balloon_3'Access,
                              Jet_1'Access);
...
for P of Pool loop
   P.Take_Off;  -- Dispatches
end loop;
```

These examples show how object orientation can be used in Ada without dynamic memory. More complicated designs, however, would probably need some form of dynamic memory and thus need to comply with the criteria listed above.

139.3.6 Exception handling

	Contributions
Objectives	• Software Design Process Objectives (A-2[4]: 5.2.1.a) • Reviews and Analyses of Software Architecture (OO.A-4[8]: OO.6.3.3.a)
Activities	• Software Design Process Activities (OO.5.2.2.k) • Reviews and Analyses of Software Architecture (OO.6.3.3)
Vulnerabilities	• Exception Management (OO.D.1.5)

An exception identifies a condition that is detected by the executing program (often implicitly by the generated code) and causes an interruption of the normal control flow and a transfer to a handler. The condition is typically an error of some sort, for example an out-of-bounds index.

Exceptions are useful in certain scenarios:

- When a program deals with externally provided data (operator input, sensor readings), the exception mechanism is a convenient way to express validity checks. A handler can perform appropriate diagnostic / recovery actions.
- When an emergency shutdown is needed for a system component, a "last chance handler" can take the appropriate measures.

However, the general exception mechanism complicates certification for several reasons:

- Typically, verification should have detected and prevented the exception from occurring in the final code. That is, exceptions can correspond to violations of preconditions, and such violations should not occur in verified code.
- Since the normal control flow has been abandoned, the program may be in an unstable state (for example with aggregate data structures not fully updated) and writing an appropriate handler can be difficult.

DO - 332/ED - 217 specifies that exception handling needs to be taken into account at the architecture level, but doesn't provide many more details. It also lists vulnerabilities

to consider; for example, an exception might not be handled properly and as a result the program could be left in an inconsistent state.

The GNAT Pro compiler supplies several strategies concerning exceptions.

- Checks can be globally deactivated. By default, execution of certain constructs (an out-of-range assignment for example) generates a run-time check. This can be removed through the `-p` option for the compiler. This should only be done after verifying that such checks cannot fail.
- If exceptions are kept but are meant to trigger an application shutdown, they can be connected to a "last chance handler". This allows the application to perform the needed finalization, such as diagnostics and logging, after which it is terminated and possibly rebooted.
- Exceptions can also be locally handled; this is achieved by specifying `pragma Restrictions (No_Exception_Propagation)`. This GNAT-specific restriction ensures that an exception is only raised when its handler is statically in the same subprogram. Exception handling can then be implemented (conceptually) by a simple branch to its handler. Such a policy is much easier to manage in a safe way than general exception propagation. Local handling is useful in situations where the software requirements specify a particular termination behavior for a subprogram under conditions that are best detected by raising an exception. An example is a "saturated add" procedure that takes two positive integers and delivers a positive integer result and an overflow status: the integer result will be the actual sum if no overflow occurred, and the maximum positive value if an overflow occurred.

```
type Overflow_Status is (No_Overflow, Overflow);

procedure Saturated_Add (I1, I2 : in Positive;
                         Result : out Positive;
                         Status : out Overflow_Status) is
begin
   Result := I1+I2;
   Status := No_Overflow;
exception
   when Constraint_Error =>
      Result := Integer'Last;
      Status := Overflow;
end Saturated_Add;
```

SPARK addresses the exception handling issue by ensuring that exceptions are never raised:

- The SPARK tools can be used to demonstrate the absence of run-time exceptions.
- Handlers are not permitted.
- Raise statements are permitted but must be proved to never execute.

139.3.7 Overloading and type conversion vulnerabilities

	Contributions
Objectives	• Reviews and Analyses of Source Code (OO.A-5[6]: OO.6.3.4.f)
Activities	• Reviews and Analyses of Source Code (OO.6.3.4)
Vulnerabilities	• Overloading (OO.D.1.3) • Type Conversion (OO.D.1.4)

Many languages allow subprogram overloading (use of the same name for different subprograms, with a call resolved based on the types of the actual parameters and possibly also the return type for a function) and implicit type conversions. This combination can

lead to readability and/or maintainability issues. For example, the application may have two functions with the same name and the same number of parameters, only distinguished by their type. In C++ this could be:

```
int f (int x);
int f (float x);

...

int r = f (100);
```

Knowing which function `f()` will be called is not immediately obvious. Furthermore, if the original version of the program contained only the declaration of `f()` with a **`float`** parameter, and the declaration of `f()` with an *int* parameter was added during maintenance, then the recompilation of `f(100)` would silently change the effect of the program to invoke the new version of `f()`.

Compiler warnings or static analysis tools are required to identify such cases and warn the user that a possibly unintended call may be made.

Such problems are much less frequent in Ada, since the language does not allow these sorts of implicit conversions. If a call is ambiguous, this is detected and the developer will need to specify the intent. Here is an example:

```
type Miles      is new Integer;
type Kilometers is new Integer;

function F (Distance : Miles)      return Integer;
function F (Distance : Kilometers) return Integer;

R : Integer := F (100);  -- Ambiguous
```

The above code is illegal in Ada due to the ambiguity: the literal 100 could be interpreted as either a `Miles` or a `Kilometers` value. A construct called *type qualification* can be used to make the type explicit and the call unambiguous:

```
R1 : Integer := F ( Miles'(100) );
R2 : Integer := F ( Kilometers'(100) );
```

With its restrictions on implicit conversions and its provision of an explicit facility for making subprogram calls unambiguous, Ada supports the necessary verification activity to mitigate the vulnerabilities in question.

139.3.8 Accounting for dispatching in performing resource analysis

	Contributions
Objectives	• Reviews and Analyses of Source Code (OO.A-5[6]: OO.6.3.4.f)
Activities	• Reviews and Analyses of Source Code (OO.6.3.4)
Vulnerabilities	• Resource analysis (OO.D.2.4)

One of the difficulties in resource analysis (worst case execution time, maximal stack usage, etc.) is how to take into account that the target of a dispatching call is unknown. This can be addressed by including resource consumption limits as part of the call requirements. E.g., each overriding version of a given subprogram must complete within a particular relative deadline, or use at most a particular amount of stack space. The usual substitutability rules would then apply; in effect such resource consumption requirements are a form of postcondition.

The GNATstack tool would provide a more pessimistic approach to worst-case stack computation, and use the maximum value required over all possible targets in its computation.

139.4 Use case #2: Using SPARK and Formal Methods

This use case is also a variant of use case #1, since the source code is developed in Ada. It thus benefits from Ada's advantages and the AdaCore ecosystem. The difference here is that the contracts, in the SPARK subset of Ada, are used to develop the low-level requirements. These contracts are amenable to formal analysis by GNATProve, which can verify consistency with the implementation.

139.4.1 Using SPARK for design data development

	Contributions
Objectives	• Software Design (A-2[3,4]: 5.2.1.a, 5.2.1.b) • Software Reviews and analyses — Requirement formalization correctness (FM.A-5[FM12]: FM.6.3.i) • Considerations for formal methods (FM.A-5[FM13]: FM.6.2.1.a, FM.6.2.1.b, FM.6.2.1.c)
Activities	• Software Development Standards (4.5) • Software Design (5.2.2.a, 5.2.2.b) • Software Reviews and analyses — Requirement formalization correctness (FM.6.3.i) • Considerations for formal methods (FM.6.2.1)

The Ada language in itself is already a significant step forward in terms of software development reliability. However, as a general-purpose language it contains features whose semantics is not completely specified (for example, order of evaluation in expressions) or which complicate static analysis (such as pointers). Large applications may need the latter, for example to define and manipulate complex data structures, to implement low-level functionality, or to interface with other languages. However, sound design principles should isolate such uses in well-identified modules, outside a safe core whose semantics is deterministic and which is amenable to static analysis. This core can be developed with much more stringent coding rules, such as those enforced in the SPARK language.

SPARK is an Ada subset with deterministic semantics, whose features are amenable to static analysis based on formal methods. For example, it excludes exception handling, side effects in functions, and aliasing (two variables referring to the same object at the same time); it limits the use of pointers (access values); and it guarantees that variables are only read after they have been initialized. Note that a SPARK program has the same run time semantics as Ada. It is compiled with a standard Ada compiler, and can be combined with code written in full Ada.

SPARK is also a superset of the Ada language in terms of statically verified specifications. A variety of pragmas and aspects can be used to define properties (contracts) such as data coupling, type invariants, and subprogram pre- and postconditions. These are interpreted by the SPARK analysis tool and do not have any effect at run-time (and thus they can be ignored by the compiler, although dynamic verification is allowed for some) but they can formally document the code and allow further static analysis and formal proof.

Even without taking advantage of SPARK's support for formal methods, coding in SPARK (or using SPARK as the basis of a code standard) helps make the software more maintainable and reliable. SPARK's contracts use the same syntax as Ada, and as just noted, a number of checks that a SPARK analysis tool could enforce statically can be enabled as run-time checks using standard Ada semantics, allowing traditional testing-based verification.

SPARK programs can be verified to have safety and security properties at various levels. For critical software, SPARK analysis can demonstrate absence of run-time errors/exceptions (such as buffer overrun and integer overflow) and ensure that variables are assigned to before they are read. In the extreme, SPARK can show that an implementation complies with a formal specification of its requirements, and this may be appropriate for some critical kernel modules. (A description of how SPARK may be introduced into a project at various levels, depending on the system's assurance requirements, may be found in a booklet co-authored by AdaCore and Thales[632].) Since subprogram pre- and postcondition contracts often express low-level requirements, some low-level requirements-based testing may be replaced by formal proofs as described in the DO - 333/ED - 216 Formal Methods supplement to DO - 178C/ED - 12C.

In summary, SPARK enhances Ada's benefits in reducing programming errors, increasing the quality and effectiveness of code reviews, and improving the overall verifiability of the code. It facilitates advanced static analysis and formal proof. At the start of a new development, considering SPARK for at least part of the application kernel can greatly decrease defects found late in the process. And when adding functionality to an existing project, SPARK can likewise bring major benefits since it allows interfacing with other languages and supports combining formal methods with traditional testing-based verification.

As part of the DO - 178C/ED - 12C processes, a manual review of the requirements translated into SPARK contracts needs to be conducted. Although SPARK can ensure that contracts are correctly and consistently implemented by the source code, the language and its analysis tools cannot verify that the requirements themselves are correct.

Another issue that needs to be taken into account is the justification of the formal method itself. It should provide a precise and unambiguous notation, and it needs to be sound (i.e., if it is supposed to identify a particular property in the source code, such as no reads of uninitialized variables, then it has to detect all such instances). The qualification material for the formal analysis tool would typically address this issue. Moreover, any assumptions concerning the formal method must be identified and justified.

139.4.2 Robustness and SPARK

	Contributions
Objectives	• Software Design (A-2[3,4,5]: 5.2.1.a, 5.2.1.b)
Activities	• Software Design (5.2.2.f)

As discussed in *Robustness / defensive programming* (page 2614), robustness is concerned with ensuring correct software behavior under abnormal input conditions. Abnormal input can come from two sources:

- External: invalid data from the operational environment (for example due to an operator input error or a hardware failure), or
- Internal: a defect in the software logic.

Behavior in the external case needs to be considered during requirements development, and from the SPARK perspective (where these requirements are captured as pre- or postconditions) there is no fundamental difference between a regular requirement and a robustness requirement. The proof performed by SPARK takes into account the entire potential input space, whether normal or abnormal.

The internal case, where faulty code passes an invalid value to a subprogram, can be detected by SPARK (GNATprove) if the validity requirement is part of the subprogram's precondition. That is, GNATprove will report its inability to prove that the subprogram invocation satisfies the precondition.

[632] AdaCore and Thales. *Implementation Guidance for the Adoption of SPARK*. AdaCore, 2020. URL: https://www.adacore.com/books/implementation-guidance-spark.

139.4.3 Contributions to Low-Level Requirement reviews

	Contributions
Objectives	• Reviews and Analyses of Low-Level Requirements (FM.A-4[2,4,5]: FM.6.3.2.b, FM.6.3.2.d, FM.6.3.2.e) • Reviews and analyses of formal analysis cases, procedures and results (FM.A-5[FM10,FM11]: FM.6.3.6.a, FM.6.3.6.b, FM 6.3.6.c)
Activities	• Reviews and Analyses of Low-Level Requirements (FM.6.3.2) • Reviews and analyses of formal analysis cases, procedures and results (FM.6.3.6.)

Using SPARK to define low-level requirements (LLRs) simplifies the verification process. Since the LLRs are expressed in a formal language (Ada 2012 or SPARK contracts), they are accurate, unambiguous, and verifiable: expressed as Boolean expressions that can be either tested or formally proven.

SPARK also makes it easier to define a software design standard, which can use the same terms and concepts as a code standard, and can be checked with similar tools.

139.4.4 Contributions to architecture reviews

	Contributions
Objectives	• Reviews and Analyses of Software Architecture (FM.A-4[9,11,12]: FM.6.3.3.b, FM.6.3.3.d, FM.6.3.3.e)
Activities	• Software Development Standards (4.5) • Reviews and Analyses of Software Architecture (FM.6.3.3)

According to DO - 333/ED - 216, the reviews and analyses of the software architecture "detect and report errors that may have been introduced during the development of the software architecture". SPARK helps meet several of the associated objectives:

- Consistency. SPARK's flow analysis contracts can specify various relationships between the software components, including a component's data dependencies and how its outputs depend on its inputs. The SPARK analysis tool (GNATprove) can then verify the correctness of these contracts / relationships, assuming TQL-5 qualification, and the consistency of the architecture. For example:

```
type Probe_Type is
   record
   ...
   end record;

Probes : array (1 .. 10) of Probe_Type;

procedure Calibrate_Probe (Index : Integer;
                           Min, Max : Integer)
   with Globals =>
          (In_Out => Probes),
        Depends =>
          (Probes => (Probes, Index, Min, Max));
```

  The `Calibrate_Probe` procedure will use the global variable `Probes` in **`in out`** mode (it can read from and write to the variable) and will compute its new value using the old value of `Probes` (at the point of call) together with the parameters `Index`, `Min` and `Max`. SPARK will verify that the only global variable used is `Probes`, and that this variable and the parameters specified in the `Depends` aspect (and no other variables) are used to compute the value.

- Verifiability. As a formal notation with tool support, SPARK can help ensure that the architecture is verifiable. One example is the protection against one component sending invalid input to another. As noted earlier, this is part of the robustness requirement that is met by SPARK's pre- and postconditions. Keeping these contracts active even in the final executable object code will protect a component from sending or receiving invalid input, and will detect any misuse.
- Conformance with standards. An architecture standard can be defined in part using similar formalisms as a code standard, thus allowing the use of similar tools for verification.

139.4.5 Contributions to source code reviews

	Contributions
Objectives	• Reviews and Analyses of Source Code (FM.A-5[1,2,3,6]: FM.6.3.4.a, FM.6.3.4.b, FM.6.3.4.c, FM.6.3.4.f)
Activities	• Software Development Standards (4.5) • Reviews and Analyses of Source Code (FM.6.3.4)

The SPARK analysis tool (GNATprove) can verify that the source code complies with its low-level requirements (LLRs) defined as SPARK contracts. This can satisfy the source code verification objectives, depending on the part of the design data formally defined:

- Compliance with the LLRs: code is proven against the LLRs
- Compliance with the architecture: code is proven against the architectural properties defined at the specification level
- Verifiability: if the code is verified by SPARK, it is verifiable. No specific activity is needed here.
- Traceability: traceability is implicit, from the LLRs defined in the specification to the implementation

The SPARK tool achieves proof in a local context; it's doing a *unit proof*. The postcondition of a subprogram will be proven according to its code and its precondition, which makes the SPARK approach scalable. For example, consider the following function:

```
type My_Array is array(Positive range <>) of Integer;

function Search (Arr   : My_Array;
                 Start : Positive;
                 Value : Integer)
   return Integer
with Pre  =>
       Start in Arr'Range,
     Post =>
       (if Search'Result = -1 then
          (for all I in Start .. Arr'Last => Arr (I) /= Value)
        else Arr(Search'Result) = Value);
```

The code inside the body might start with:

```
function Search (Arr   : My_Array;
                 Start : Positive;
                 Value : Integer)
   return Integer is
begin
   if Arr (Start) = Value then
      return Start;
```

(continues on next page)

(continued from previous page)

```
   end if;
   ...
```

Because of the precondition, the SPARK analysis tool can deduce that the array indexing will not raise an exception.

Here's another piece of code, responsible for replacing all occurrences of one value by the other:

```
procedure Replace (Arr  : in out My_Array;
                   X, Y : in Integer)
with Pre  => Arr'Length /= 0 and X /= Y,
     Post => (for all I in Arr'Range =>
                 (if Arr'Old (I) = X then Arr (I) = Y));

procedure Replace (Arr : in out My_Array; X, Y : Integer) is
   Ind : Integer := Arr'First;
begin
   loop
      Ind := Search (Arr, Ind, X);
      exit when Ind = -1;
      Arr (Ind) := Y;
      exit when Ind = Arr'Last;
   end loop;
end Replace;
```

When `Search` is invoked, the only things that the prover knows are its pre- and postconditions. It will attempt to show that the precondition is satisfied, and will assume that the postcondition is `True`. Whether or not `Search` is proven doesn't matter at this stage. If it can't be proven with the SPARK tools, we may decide to verify it through other means, such as testing.

The SPARK analysis tools can demonstrate absence of run-time errors, absence of reads of uninitialized variables, absence of unused assignments, and other properties. Additional contracts may sometimes be needed for assistance (e.g., assertions), but overall SPARK's restricted feature set and advanced proof technology automate contract proofs with very few cases needing to be manually dismissed. This almost entirely replaces manual reviews and analyses.

The analysis performed by SPARK is usually very tedious to conduct by manual review. As an example, here's a simple piece of code:

```
subtype Some_Int is Integer range ...;
Arr : array (Integer range <>) of Some_Int := ...;

Index, X, Y, Z : Integer;
...
Arr (Index) := (X * Y) / Z;
```

Exhaustive analysis of all potential sources of errors requires verifying that:

- `X` is initialized
- `Y` is initialized
- `Z` is initialized
- `Index` is initialized and is in `Arr'Range`
- `(X * Y)` does not overflow
- `Z` is not equal to zero
- `(X * Y) / Z` is within the range of `Some_Int`

The GNATprove tool will check each of these conditions, and report any that might not hold.

139.4.6 Formal analysis as an alternative to low-level testing

	Contributions
Objectives	• Software Testing (A-6[3,4]: 6.4.c, 6.4.d)
Activities	• Low Level testing (6.4.3.c)

As stated in Section 6.4 of DO - 178C/ED - 12C, the purpose of software testing is "to demonstrate that the software satisfies its requirements and to demonstrate ... that errors that could lead to unacceptable failure conditions ... have been removed". Thus it's not the source code but the binary code that is tested, and within an environment representative of the final target. As a consequence, the compiler itself is not part of the trusted chain. Since its outputs are verified, it can be assumed to be correct within the exact conditions of the certified system.

Various activities in DO - 178C/ED - 12C increase the confidence in the compilation step, such as selecting an appropriate set of options, assessing the effect of its known problems and limitations, and (at software level A) verifying the correctness of non-traceable code patterns.

DO - 333/ED - 216 explains how certain classes of testing can be replaced by formal analysis ("proof"). When low level requirements are expressed as formal properties of the code, it's possible to formally verify that the source code completely implements the requirements. Using this technique, however, requires additional activities to demonstrate absence of unintended function. Further, and more significantly, with formal analysis it's the source code that is checked against requirements, not the object code. As a result, additional activities are required to demonstrate correct behavior of the object code. This is the so-called *property preservation* issue, discussed in *Property preservation between source code and object code* (page 2645).

139.4.7 Low-level verification by mixing test and proof ("Hybrid verification")

	Contributions
Objectives	• Software Testing (A-6[3,4]: 6.4.c, 6.4.d)
Activities	• Low Level testing (6.4.3.c)

It is not always possible for the SPARK proof tool to prove all the contracts in an application. When this is due to limited capabilities in the proof technology, manually provided assistance may be a solution. However, some assertions and contracts might not be provable at all. This could be due to several factors:

- The specification is in SPARK but the actual implementation is in a different language (such as C).
- The contract or implementation uses Ada features outside of the SPARK subset.
- Some constructs might not be amenable to formal proof, even if correct, because a piece of code is too complex.
- Some final proof step may be hard to reach, requiring an effort that is excessive compared to some other verification technique.

For all of these reasons, a combination of proof and testing may be appropriate to fully verify the software. The basic principle is that SPARK proofs are local. They're performed assuming that each called subprogram fulfills its contracts: if its precondition is satisfied

and the subprogram returns, then its postcondition will hold. If this correctness is demonstrated by formal proof, then the whole program is proven to comply with all contracts. However, correctness may also be demonstrated by testing. In this case, the dual semantics of contracts, dynamic and static, is key. The pre- and postconditions can be enabled as run-time checks to verify the expected output of the test procedures.

An efficient approach during the design process is to define an architecture that distinguishes between those components verified by formal proofs and those verified by testing. Mixing the two techniques is sometimes referred to as *hybrid verification*.

139.4.8 Alternatives to code coverage when using proofs

	Contributions
Objectives	• Principles of Coverage Analysis when using Formal Methods (FM.A-7[FM5-8]: FM.6.7.1.c)
Activities	• Requirement-Based Coverage Analysis (FM.6.7.1.2, FM.6.7.1.3, FM.6.7.1.4, FM.6.7.1.5)

Structural code coverage is a test-based activity for verifying the exhaustivity of the testing, the completeness of the requirements, and the absence of unintended function (extraneous code, including dead code). With formal proofs, a different set of activities is needed to meet similar objectives. DO - 333/ED - 216 lists four activities to be performed:

- Complete coverage of each requirement. This objective is to verify that each assumption made during the analysis is verified. In SPARK, these assumptions are easily identifiable. These are typically assertions in the code that cannot be proven automatically, for example because they are too complex or involve interfacing with non-SPARK code. These assumptions can be verified not with proofs but with alternative means such as testing and reviews.
- Completeness of the set of requirements. In particular, for each input condition its corresponding output condition has been specified, and vice versa. This can be achieved, for example, by specifying dependency relationships between input and output (the SPARK aspect `Depends`) or by partitioning the input space (the SPARK aspect `Contract_Case`).
- Detection of unintended dataflow relationships. The SPARK aspect `Depends` will verify that each output is computed from its specified set of inputs.
- Detection of extraneous code. If the requirements are complete and all output variables (and their dependencies) are specified in these requirements, then any extraneous code should be dead and have no unintended effect. A manual review of the code will help achieve confidence that no such code is present.

139.4.9 Property preservation between source code and object code

	Contributions
Objectives	• Verification of Property Preservation Between Source and Executable Object Code (FM.A-7[FM9]: FM.6.7.f)
Activities	• Verification of Property Preservation Between Source and Executable Object Code (FM.6.7.f -1)

When part of the executable object code (EOC) verification is performed using formal proof instead of testing, the source code is verified against the requirements, but the compiler

is out of the loop. As a result, additional activities need to be performed to confirm proper translation of the source code to object code.

This is an open topic, and several approaches are possible to achieve credit for preservation of properties. One possibility is to perform an analysis of the compiler's processing similar to the source-code-to-object-code traceability study that addresses DO - 178C/ED - 12C §6.4.4.2.b. However, in addition to analyzing and justifying instances of non-traceability, the behavior of traceable code also needs to be considered / verified.

An alternative solution is to rely on the fact that SPARK functional contracts are executable Ada expressions. These are the actual properties that need to be preserved between source code and EOC. One way to demonstrate property preservation is to run the tests based on a higher level of requirements (such as Software / Software integration testing) once, with contract checks activated. If no contract failure occurs, we can conclude that the expected behavior has been properly translated by the compiler. This gives sufficient confidence in the code generation chain.

Running tests to verify this activity may seem to defeat the purpose of replacing testing by proof. However, this should not be considered as requirement-based testing (which is indeed replaced by proof). This *property preservation* verification is a confirmation of the formal analysis by executing the EOC with contract checking enabled.

139.4.10 SPARK Development Cycle Example

An example in Appendix B of DO - 333/ED - 216 — "FM.B.1.5.1 Unit Proof" — shows how the use of formal methods (in this case the CAVEAT tool for C, based on Hoare logic) can help meet various DO - 333/ED - 216 objectives. The same example can be expressed in SPARK, with the same contributions towards DO - 333/ED - 216 compliance.

The High-Level Requirements define the intent of the example; viz., to check the contents of a flash zone:

- verify that the whole flash zone is initialized to the value 0xFF
- if a memory location is different from 0xFF, the check has failed

The Low-Level Requirements comprise a textual description and a set of formal properties. The textual description appears in DO - 333/ED - 216 and is not repeated here. The formal properties of the A1F2_TestZone procedure are of three kinds:

- *Global* contract: identifies the dependence on external data
- *Post* contract: the postcondition for the procedure
- *Loop_Invariant* pragma: a condition that holds at each iteration

```
with Global => (Input => A1F2_Memory_Zone),
     Post =>
         -- COND_FCT
       ((for all K in T_A1F2_Index => A1F2_Memory_Zone(K) = 16#FF#) and then
         Rl_Return = OK and then pFailure.FailureIndex = INDEX_NO_ERROR) or else
         -- COND_ERR
       ((for some K in T_A1F2_Index => A1F2_Memory_Zone(K) /= 16#FF#) and then
          Rl_Return = NOT_OK and then pFailure.FailureIndex = INDEX_FLASH_2);

pragma Loop_Invariant(for all K in T_A1F2_Index'First .. Rl_Index =>
                      A1F2_Memory_Zone(K) = Rl_Expectedvalue);
pragma Loop_Invariant(pFailure = APAT_Ce_sFAILURE_NO_ERROR
                        and then
                      Rl_Return = OK);
```

Here is the source code for the package spec (a1f2.ads) and body (a1f2.adb):

```
package A1F2 with SPARK_Mode is
   -- Type declarations ------------------------------------------------------
   type T_RESULT is (OK, NOT_OK);
   type T_FAILURES is (NCD, INDEX_NO_ERROR, INDEX_FLASH_2);

   -- 32-bit word type for hardware interaction
   type T_WORD32 is mod 2**32;
   for T_WORD32'Size use 32;

   -- Error descriptor record ------------------------------------------------
   --  Record containing several fields that are used to store information about
   --  the type of failure that occurred.
   type T_FAILURE_DESCRIPTOR is record
      FailureIndex  : T_FAILURES;
      VmemoryState2 : T_WORD32;
      VmemoryState3 : T_WORD32;
      VmemoryState4 : T_WORD32;
      VmemoryState5 : T_WORD32;
   end record;

   -- Array type for memory zone ---------------------------------------------
   A1F2_ZONE_SIZE : constant := 1024;  -- Adjust based on your actual memory size
   subtype T_A1F2_Index is Integer range 0 .. A1F2_ZONE_SIZE - 1;
   type T_A1F2_MEMORY_ZONE is array (T_A1F2_Index) of T_WORD32;

   -- Hardware memory mapping ------------------------------------------------
   A1F2_Memory_Zone : T_A1F2_MEMORY_ZONE;
   --  pragma Volatile(A1F2_Memory_Zone);  -- Ensure no optimizations on memory␣
↪access
   --  pragma Import(Convention => Ada, Entity => A1F2_Memory_Zone);

   -- Constants --------------------------------------------------------------
   APAT_Ce_sFAILURE_NCD     : constant T_FAILURE_DESCRIPTOR := (
      FailureIndex  => NCD,
      VmemoryState2 => 0,

As with the example in DO - 333/ED - 216, the use of SPARK contributes to meeting the following objectives. In some cases additional verification activity is needed, and, as noted in the DO - 333/ED - 216 example, "functional tests are always required to establish correctness of the overall system."

- Table FM.A-4, Objective FM17: Formal method is correctly defined, justified, and appropriate
- Table FM.A-5, Objective FM13: Formal method is correctly defined, justified, and appropriate
- Table FM.A-7, Objective FM10: Formal method is correctly defined, justified, and appropriate
- Table FM.A-4, Objective FM16: Requirement formalization is correct
- Table FM.A-4, Objective 2: Low-level requirements are accurate and consistent
- Table FM.A-4, Objective 5: Low-level requirements conform to standards
- Table FM.A-5, Objective 1: Source code complies with low-level requirements
- Table FM.A-5, Objective FM-10: Formal analysis cases and procedures are correct
- Table FM.A-5, Objective FM-11: Formal analysis results are correct and discrepancies explained
- Table FM.A-6, Objective 3: Executable object code complies with low-level requirements
- Table FM.A-6, Objective 4: Executable object code is robust with low-level requirements
- Table FM.A-7, Objective FM 4: Coverage of low-level requirements is achieved
- Table FM.A-7, Objective FM 5-8: Verification of software structure is achieved
- Table FM.A-7, Objective FM 9: Verification of property preservation between source and object code

139.5 Parameter Data Items

	Contributions
Objectives	• Software requirements process (A-2[1]: 5.1.1.a) • Software integration process (A-2[7]: 5.4.1.a) • Verification of Parameter Data Items (A-5[8,9]: 6.6)
Activities	• Software requirements process (5.1.2.j) • Software Integration process (5.4.2.a) • Verification of Parameter Data Items (6.6.a), (6.6.b)

The term "Parameter Data Item" (PDI) in DO - 178C/ED - 12C refers to a set of parameters that influence the behavior of the software without modifying the Executable Object Code. The verification of a parameter data item can be conducted separately from the verification of the Executable Object Code.

PDI development implies the production of three kinds of data:

- The "structure and attributes": These define the characteristics of each item, such as its type, range, or set of allowed values. In order to ensure the data item correctness and consistency, a set of consistency rules should also be defined. For example, if one item defines the number of temperature sensors, and other items define the characteristics of each sensor, there is an obvious relationship between these items.
- The specification of an instance of a PDI: The defined set of values for each item for an applicable configuration
- The PDI file that implements an instance of a PDI directly usable by the processing unit of the target computer (e.g. a binary file)

An efficient way to develop such artifacts is to use Ada and/or SPARK.

The structure and attributes can be defined in one or more package specifications. Each item is defined with its type, defining range and set of allowed values. Predicates can be used to define relationships between parameters. The example below combines a classical approach using strong typing and type ranges, with a dynamic predicate to describe relationships between components of the structure. The intent is to specify the accepted range of temperatures for a given sensor.

```
type Sensor is
   record
      Min_Temp : Float range -40.0 .. 60.0;
      Max_Temp : Float range -20.0 .. 80.0;
   end record
with Dynamic_Predicate => Sensor.Min_Temp < Sensor.Max_Temp;
```

Each PDI instance needs to satisfy the constraints expressed in the `Dynamic_Predicate` aspect. These constraints are based on a higher-level specification, such as customer-supplied requirements, a system configuration description, or an installation file. Generating the PDI file for an instance consists in using GNAT Pro to compile/link the Ada source code for the PDI, producing a binary file.

Verifying the correctness of a PDI instance (compliance with structure and attributes) can be automated by compiler checks. This means that inconsistencies will be detected at load time. For example,

```
S1 : Sensor := (Min_Temp => -30.0, Max_Temp => 50.0);
S2 : Sensor := (Min_Temp => -50.0, Max_Temp => 50.0);
S3 : Sensor := (Min_Temp =>  40.0, Max_Temp => 30.0);
```

S1 will be accepted, S2 will not (`Min_Temp` is out of range), S3 will not (`Min_Temp` is above `Max_Temp`). (The `Dynamic_Predicate` check can also be enabled as a run-time check, via `pragma Assertion_Policy(Check)` and the `-gnata` switch to the GNAT compiler.) If all PDIs are defined in this manner, completeness of verification is ensured.

The only remaining activity is to check that the PDI instance value complies with the system configuration.

SUMMARY OF CONTRIBUTIONS TO DO-178C/ED-12C OBJECTIVES

140.1 Overall summary: which objectives are met

The following tables summarize how the Ada and SPARK languages and AdaCore's tools help meet the objectives in DO - 178C/ED - 12C and the technology supplements. The numbers refer to the specific objectives in the core document or the relevant supplement.

Table A-3 and Tables A-8 through A-10 are not included, since they are independent of AdaCore's technologies.

140.1.1 Mapping of AdaCore's Technologies to DO-178C/ED-12C Objectives

Table 2: Overall Summary, Part 1 - Which DO - 178C/ED - 12C objectives are met by AdaCore's Technologies

140.2 Detailed summary: which activities are supported

In the tables below, the references in the Activities column are to sections in DO - 178C/ED - 12C or to one of the technology supplements. The references in the Use case columns are to sections in this document.

Since AdaCore's tools mostly contribute to the bottom stages of the *V* cycle (design, coding, integration and related verification activities), verification of High-Level Requirements (and thus Table A-3) are outside the scope of AdaCore solutions.

Likewise, the objectives in Table A-8 (Configuration Management), A-9 (Quality Assurance) and A-10 (Certification Liaison Process) are independent of AdaCore's technologies; they are the responsibility of the user.

140.2.1 Table A-1: Software Planning Process

The objectives of the Software Planning process are satisfied by developing software plans and standards. These activities are the responsibility of the software project. However, using AdaCore solutions can reduce the effort in meeting some of these objectives.

Objective	Summary	Activities	Use case #1a	Use case #1b (OOT)	Use case #2
1	The activities of the software life cycle processes are defined	All	This document describes possible methods and tools that may be used. When an AdaCore solution is adopted, it should be documented in the plans.	Same as #1a	Same as #1a
2	The software life cycle(s), including the inter-relationships between the processes, their sequencing, and transition criteria, is defined.	All	A variety of software life cycles may be defined (such as V cycle, Incremental, Iterative, and Agile). AdaCore solutions do not require any specific software life cycle.	Same as #1a	Same as #1a
3	Software life cycle environment is selected and defined	4.4.1.a, 4.4.1.f, 4.4.2.b, 4.4.3.a, 4.4.3.b	When an AdaCore solution is used, the plans should identify and describe the associated tools. In particular, see *Sustained Branches* (page 2593) and *Compiling with the GNAT Pro compiler* (page 2618)	Same as #1a	Same as #1a
4	Additional considerations are addressed	4.2.j, 4.2.k	The need for tool qualification is addressed throughout this document.	Same as #1a	Same as #1a

continues on next page

Table 4 – continued from previous page

5	Software development standards are defined.	4.2.b, 4.5.b, 4.5.c, 4.5.d	This document describes possible languages, methods and tools that may be used during the design and coding processes. When any of them are used, design and code standards must be developed accordingly. A Code Standard can be defined through *GNATcheck* (page 2596)	Same as #1a	Same as #1a
6	Software plans comply with this document.	All	This objective is satisfied through the review and analysis of the plans and standards.	Same as #1a	Same as #1a
7	Development and revision of software plans are coordinated.	All	This objective is satisfied through the review and analysis of the plans and standards.	Same as #1a	Same as #1a

140.2.2 Table A-2: Software Development Processes

AdaCore tools mostly contribute to the bottom stages of the traditional *V* cycle (design, coding, integration, and the related verification activities).

Objective	Description	Activities	Use case #1a	Use case #1b (OOT)	Use case #2
1	High-level requirements are developed	5.1.2.j	Outside the scope of AdaCore solutions, except for *Parameter Data Items* (page 2649)	Same as #1a	Same as #1a
2	Derived high-level requirements are defined and provided to the system processes, including the system safety assessment process.		Outside the scope of AdaCore solutions	Same as #1a	Same as #1a

Table 5 – continued from previous page

3	Software architecture is developed.	5.2.2.a	See *Using Ada during the design process* (page 2607)	See *Object orientation for the architecture* (page 2627), *Memory management issues* (page 2634), *Exception handling* (page 2636)	See *Using SPARK for design data development* (page 2639)
4	Low-level requirements are developed.	5.2.2.a	See *Using Ada during the design process* (page 2607)	See *Dealing with dynamic dispatching and substitutability* (page 2629)	See *Using SPARK for design data development* (page 2639), *Robustness and SPARK* (page 2640)
5	Derived low-level requirements are defined and provided to the system processes, including the system safety assessment process	5.2.2.b	See *Using Ada during the design process* (page 2607)	See *Dealing with dynamic dispatching and substitutability* (page 2629)	See *Using SPARK for design data development* (page 2639), *Robustness and SPARK* (page 2640)
6	Source code is developed	All	See *Benefits of the Ada language* (page 2602), *Integration of C components with Ada* (page 2613), *Robustness / defensive programming* (page 2614)	Same as #1a	See *Benefits of the Ada language* (page 2602)
7	Executable Object Code and Parameter Data Files, if any produced and loaded in the target computer.	5.4.2.a, 5.4.2.b, 5.4.2.d	See *Compiling with the GNAT Pro compiler* (page 2618), *Integration of C components with Ada* (page 2613), *Parameter Data Items* (page 2649)	Same as #1a	Same as #1a

140.2.3 Table A-4: Verification of Outputs of Software Design Process

AdaCore solutions may contribute to the verification of the architecture and Low-Level Requirements when Ada/SPARK is used during design process. However, compliance with High-Level Requirements is not addressed by AdaCore solutions.

Objective	Description	Activities	Use case #1a	Use case #1b (OOT)	Use case #2
1	Low-level requirements comply with high-level requirements.	6.3.2	Outside the scope of AdaCore solutions, except for *Parameter Data Items* (page 2649)	Same as #1a	Same as #1a
2	Low-level requirements are accurate and consistent	6.3.2			See *Contributions to Low-Level Requirement reviews* (page 2641)
3	Low-level requirements are compatible with target computer.	6.3.2	See *Implementation of Hardware / Software Interfaces* (page 2611)		
4	Low-level requirements are verifiable.	6.3.2			See *Contributions to Low-Level Requirement reviews* (page 2641)
5	Low-level requirements conform to standards.	6.3.2			See *Contributions to Low-Level Requirement reviews* (page 2641)
6	Low-level requirements are traceable to high-level requirements.		Outside the scope of AdaCore solutions	Same as #1a	Same as #1a
7	Algorithms are accurate.	6.3.2	See *Using Ada during the design process* (page 2607)	Same as #1a	See *Contributions to Low-Level Requirement reviews* (page 2641)
8	Software architecture is compatible with high-level requirements.	6.3.3		See *Memory management issues* (page 2634), *Exception handling* (page 2636)	
9	Software architecture is consistent.	6.3.3			See *Contributions to architecture reviews* (page 2641)

140.2.5 Table A-6 Testing of Outputs of Integration Process

Objective	Description	Activities	Use case #1a	Use case #1b (OOT)	Use case #2
1	Executable Object Code complies with high-level requirements.		This objective is outside the scope of AdaCore solutions	Same as #1a	Same as #1a
2	Executable Object Code is robust with high-level requirements.		This objective is outside the scope of AdaCore solutions	Same as #1a	Same as #1a
3	Executable Object Code complies with low-level requirements.	6.4.2, 6.4.2.1, 6.4.3, 6.5	See *Using GNATtest for low-level testing* (page 2619), *Using GNATemulator for low-level and software / software integration tests* (page 2622)	See *Formal analysis as an alternative to low-level testing* (page 2644), *Low-level verification by mixing test and proof ("Hybrid verification")* (page 2644)	
4	Executable Object Code is robust with low-level requirements.	6.4.2, 6.4.2.2, 6.4.3, 6.5	See *Using GNATtest for low-level testing* (page 2619), *Using GNATemulator for low-level and software / software integration tests* (page 2622), *Robustness / defensive programming* (page 2614)	Same as #1a	See *Formal analysis as an alternative to low-level testing* (page 2644), *Low-level verification by mixing test and proof ("Hybrid verification")* (page 2644)
5	Executable Object Code is compatible with target computer.		This objective is based on High-Level Requirements and is thus outside the scope of AdaCore solutions	Same as #1a	Same as #1a

140.2.6 Table A-7 Verification of Verification Process Results

Use case #2 applied formal analysis to verify compliance with Low-Level Requirements. In applying DO - 333/ED - 216, objectives 4 to 7 from DO - 178C/ED - 12C are replaced with objectives FM 1 to FM 10.

Objective	Description	Activities	Use case #1a	Use case #1b (OOT)	Use case #2
1	Test procedures are correct.	6.4.5	See *Using GNATtest for low-level testing* (page 2619)	Same as #1a	Limited to verification not performed by formal analysis
2	Test results are correct and discrepancies explained.	6.4.5	See *Using GNATtest for low-level testing* (page 2619)	Same as #1a	Limited to verification not performed by formal analysis
3	Test coverage of high-level requirements is achieved.		This objective concerns the verification of High-Level Requirements and thus is outside the scope of Adacore solutions	Same as #1a	Same as #1a
4	Test coverage of low-level requirements is achieved.	6.4.4.1		See *Coverage in the case of generics* (page 2627)	
5	Test coverage of software structure (modified condition / decision coverage) is achieved.	6.4.4.2.a 6.4.4.2.b	See *Structural code coverage with GNATcoverage* (page 2622), *Coverage in the case of generics* (page 2627)		
6	Test coverage of software structure (design coverage) is achieved.	6.4.4.2.a 6.4.4.2.b	See *Structural code coverage with GNATcoverage* (page 2622), *Coverage in the case of generics* (page 2627)		
7	Test coverage of software structure (statement coverage) is achieved.	6.4.4.2.a 6.4.4.2.b	See *Structural code coverage with GNATcoverage* (page 2622), *Coverage in the case of generics* (page 2627)

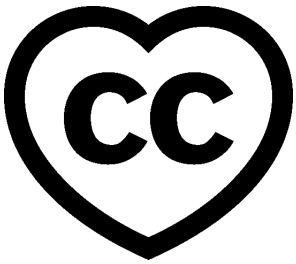
140.3 AdaCore Tool Qualification and Library Certification

Qualification material can be developed for GNATstack and is available for GNATcheck and GNATcoverage:

Tool	TQL	DO - 178C/ED - 12C Objectives / Activities	DO - 330/ED - 215 Objectives / Activities
GNATstack	TQL-5	A-5[6]: 6.3.4.f	
GNATcheck	TQL-5	A-5[4]: 6.3.4.d	T-5[1..6y]: 6.1.3.4.d
GNATcoverage	TQL-5	A-7[5..9]: 6.4.4.2	T-7[5..9]: 6.1.4.3.2.a



Certification material up to Software Level A can be developed for the Light and Light-Tasking run-time libraries.

About the Authors

Jean-Louis Boulanger

Since the late 1990s Jean-Louis Boulanger has been an independent safety assessor for the CERTIFER certification authority in France, for safety-critical software in railway systems. He is an experienced safety expert in both the railway industries with the CENELEC standard and the automotive domain with ISO 26262. He has published a number of books on the industrial use of formal methods, as well as a book on safety for hardware architectures and a recent book on the application of the CENELEC EN 50128 and IEC 62279 standards. He has also served as a professor and researcher at the University of Technology of Compiègne.

Quentin Ochem

Quentin Ochem is the Chief Product and Revenue Officer at AdaCore, where he oversees marketing, sales, and product management while steering the company's strategic initiatives. He joined AdaCore in 2005 to work on the company's Integrated Development Environments and cross-language bindings. With an extensive background in software engineering in high-integrity domains such as avionics and defense, he has served leading roles in technical sales, customer training, and product development. Notably, he has conducted training on the Ada language, AdaCore tools, and the DO - 178B/ED - 12B and DO - 178C/ED - 12C software certification standards. In 2021 he stepped into his current role, directing the company's strategic initiatives.

Foreword

The guidance in the CENELEC standard EN 50128:2011 helps achieve confidence that railway control and protection software meets its safety requirements. Certifying compliance with this standard is a challenging task, especially for the testing and verification activities, but appropriate usage of qualified tools and specialized run-time libraries can significantly simplify the effort. This document explains how a number of technologies offered by AdaCore — tools, libraries, and supplemental services — can help. The content is based on the authors' many years of practical experience with the certification of railway software and with the Ada and SPARK programming languages.

Jean-Louis Boulanger
October 2015

Quentin Ochem, AdaCore
October 2015

Foreword to V2.1

In the years since the initial version of this document was published, the EN 50128:2011 standard has been amended twice, and AdaCore's products have evolved to meet the growing demands for, and challenges to, high assurance in mission-critical real-time software. This revised edition reflects the current (2025) versions of EN 50128 and AdaCore's offerings. Among other updates and enhancements to the company's products, the static analysis tools supplementing the GNAT Pro development environment have been integrated into a cohesive toolset (*CodeSonar for Ada*). The dynamic analysis tools have likewise been consolidated, and the resulting *GNAT Dynamic Analysis Suite* has introduced a fuzzing tool — *GNATfuzz* — which exercises the software with invalid input and checks for failsafe behavior.

As editor of this revised edition, I would like to thank Vasiliy Fofanov (AdaCore) for his detailed and helpful review and suggestions.

For up-to-date information on AdaCore support for developers of rail software, please visit[634].

CHAPTER

ONE

INTRODUCTION

141.1 CENELEC safety-related railway standards

Railway projects are subject to a legal framework (laws, decrees, etc.) and also a normative process based on certification standards. In Europe, these standards are issued and maintained by CENELEC (European Committee for Electrotechnical Standardization). This document explains the usage of AdaCore's technologies in conjunction with EN 50128:2011[635] — *Railway applications - Communication, signalling and processing systems - Software for railway control and protection systems* — as modified by amendments EN 50128/A1[636] and EN 50128/A2[637]. (For ease of exposition, the 2011 edition of the standard, as modified by the A1 and A2 amendments, will simply be referred to as EN 50128.)

EN 50128 is concerned with the safety-related aspects of a railway system, down to the hardware and/or software elements used. This document will cover where AdaCore's technologies fit best and how they can best be applied to meet various requirements in this standard.

EN 50128 is based on fundamentals described in other CENELEC railway standards:

- EN 50126-1[638] — *Railway applications - The specification and demonstration of reliability, availability, maintainability and safety (RAMS) - Part 1: Generic RAMS process* (subsequently modified by EN 50126-1/A1[639])
- EN 50126-2[640] — *Railway applications - The specification and demonstration of reliability, availability, maintainability and safety (RAMS): Part 2: systems approach to safety*
- EN 50129[641] — *Railway applications - Communication, signalling and processing systems - Safety related electronic systems for signalling*

As noted in EN 50128, page 7:

> *EN 50126-1 addresses system issues on the widest scale, while EN 50129 addresses the approval process for individual systems which can exist within the overall railway control and protection system. ... [EN 50128] concentrates on the methods which need to be used in order to provide software which meets the*

[635] *EN 50128: Railway applications – Communications, signalling and processing systems – Software for railway control and protection systems*. CENELEC, 2011.
[636] *EN 50128/A1: Railway applications – Communications, signalling and processing systems – Software for railway control and protection systems*. CENELEC, February 2020.
[637] *EN 50128/A2: Railway applications – Communications, signalling and processing systems – Software for railway control and protection systems*. CENELEC, July 2020.
[638] *EN 50126-1: Railway applications - The specification and demonstration of reliability, availability, maintainability and safety (RAMS)- Part 1: Generic RAMS process*. CENELEC, October 2017.
[639] *EN 50126-1/A1: Railway applications - The specification and demonstration of reliability, availability, maintainability and safety (RAMS) - Part 1: Generic RAMS process*. CENELEC, 2024.
[640] *EN 50126-2: Railway applications - The specification and demonstration of reliability, availability, maintainability and safety (RAMS)- Part 2: systems approach to safety*. CENELEC, October 2017.
[641] *EN 50129: Railway applications - Communication, signalling and processing systems - Safety related electronic systems for signalling*. CENELEC, November 2018.

demands of safety integrity which are placed upon it by these wider considerations.

In addition to EN 50126 and EN 50129, several other CENELEC standards relate to software's role in the safety of a railway system:

- EN 50657:2017[642] as modified by amendment EN 50657/A1[643] — *Railways applications - Rolling stock applications - Software on Board Rolling Stock*

  This standard extends the principles of EN 50128 into the rolling stock domain, focusing on onboard systems such as braking, door control, and driver interfaces.

  It retains RAMS goals but tailors them for embedded systems in motion, where environmental and operational variables are more dynamic.

- EN 50716:2023[644] — *Railway Applications - Requirements for software development*

  This standard is a successor to EN 50128 and EN 50657, providing better alignment with EN 50126-1 and EN 50126-2. As of 2025 it is at the early adoption stage but is intended to supersede both EN 50128 and EN 50657.

Fig. 4 depicts the relationships among the various standards.

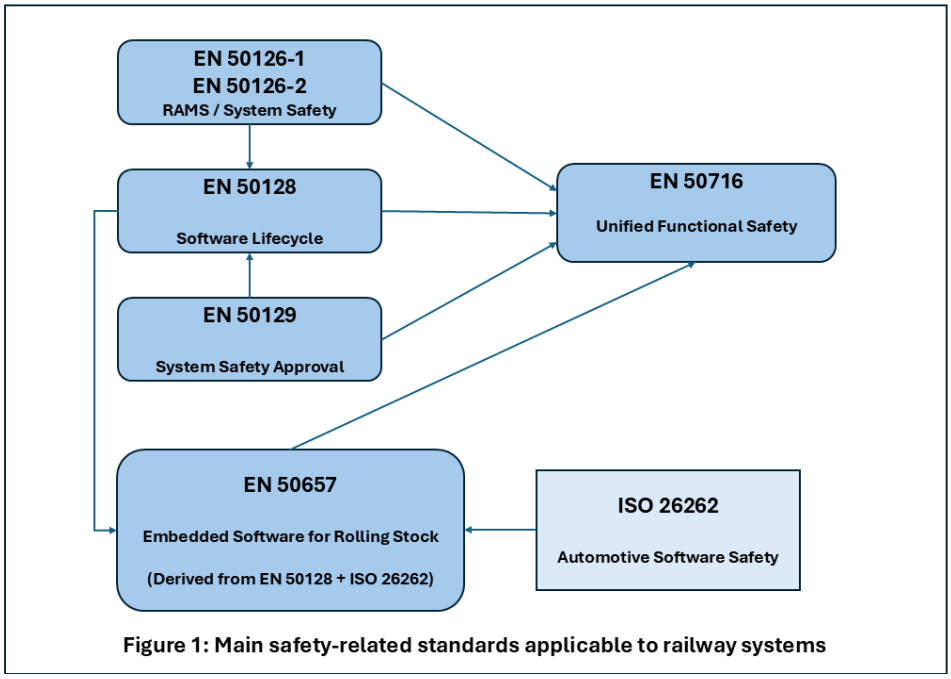

Fig. 4: Relationships among the various standards

141.2 Safety Integrity Levels

A key concept in EN 50128 is the *Safety Integrity Level* (SIL) of a software component, which reflects the risk of a hazard occurring if the software fails. If there is no impact on safety, the level is referred to as "Basic Integrity" (earlier known as SIL 0). Otherwise the level has a value between 1 and 4, where 4 is the most critical; i.e., with the highest risk of a hazard in case of software failure.

[642] *EN 50657: Railways applications – Rolling stock applications - Software on Board Rolling Stock*. CENELEC, August 2017.
[643] *EN 50657/A1: Railways applications – Rolling stock applications - Software on Board Rolling Stock*. CENELEC, November 2023.
[644] *EN 50716: Railway applications – Requirements for software development*. CENELEC, November 2023.

EN 50128 defines the techniques/measures that need to be used at various software life cycle stages, based on the applicable SIL.

141.3 AdaCore technologies for railway software

AdaCore's technologies revolve around programming activities, as well as the closely related design and verification activities. This is the bottom of the "V" cycle as defined in EN 50128, sub-clause 5.3, Figure 4 (see Fig. 5 below). The company's tools exploit the features of the Ada language (highly recommended by table A.15) and its formally verifiable SPARK subset. In particular, the 2012 version of the Ada standard includes some significant capabilities in terms of specification and verification.

AdaCore's technologies bring two main benefits to the software life cycle processes defined by the CENELEC railway standards.

- *Expressing software interface specifications and software component specifications directly in the source code.*

  Interfaces can be precisely expressed through standard syntax for features such as strong typing, parameter constraints, and subprogram contracts. These help to clarify interface documentation, to enforce program constraints and invariants, and to provide an extensive foundation for software component and integration verification.

- *Reducing the verification costs.*

  Bringing additional specification at the language level allows verification activities to run earlier in the software life cycle, during the software component implementation itself. Tools provided by AdaCore support this effort and are designed to be equally usable by both the development team and the verification team. Allowing developers to use verification tools greatly reduces the number of defects found at the verification stage and thus reduces costs related to change requests identified in the ascending stages of the cycle.

AdaCore's technologies can be used at all Safety Integrity Levels, from Basic Integrity to SIL 4. At lower levels, the full Ada language is suitable, independent of platform. At higher levels, specific subsets will be needed, for example the Ravenscar Profile ([645],[646]) for concurrency support with analyzable semantics and a reduced footprint, or the Light Profile[647] for a subset with no run-time library requirements. At the highest level (SIL 4) the SPARK language ([646],[648]) and its verification toolsuite enable mathematical proof of properties including correct information flow, absence of run-time exceptions, and, for the most critical code, correctness of the implementation against a formally defined specification.

The following technologies will be presented:

- *Ada*, a compilable programming language supporting imperative, object-oriented, and functional programming styles and offering strong specification and verification features. Unless otherwise indicated, "Ada" denotes the 2012 version of the Ada language standard.
- *SPARK*, an Ada language subset and toolset supporting formal verification of program properties such as Absence of Run-Time Errors
- *GNAT Pro Assurance*, a specialized edition of AdaCore's GNAT Pro language development environments that is oriented towards projects with long maintenance cycles or certification requirements

[645] Alan Burns, Brian Dobbing and Tullio Vardanega. Guide for the use of the Ada Ravenscar Profile in high integrity systems. *Ada Letters*, June 2004.

[648] *SPARK Reference Manual, Release 2020*. AdaCore and Altran, 2020. URL: https://www.adacore.com/uploads/techPapers/spark_rm_community_2020.pdf.

- *CodeSonar for Ada*, comprising several tools:
  - A "bug finder" engine that identifies potential defects and vulnerabilities in Ada code
  - GNATmetric — a metric computation tool
  - GNATcheck — a coding standard checker
- The *GNAT Dynamic Analysis Suite* ("GNAT DAS"), comprising several tools:
  - GNATtest — a unit testing framework generator
  - GNATemulator — a processor emulator
  - GNATcoverage — a structural code coverage analyzer
  - GNATfuzz — a fuzzing tool that helps uncover potential faults
  - TGen — an experimental run-time library for automating test case generation
- *GNAT Pro for Rust*, a professionally supported complete development environment for the Rust programming language
- Several *Integrated Development Environments* (IDEs):
  - GNAT Studio — a robust, flexible, and extensible IDE
  - VS Code support — extensions for Ada and SPARK
  - GNATbench — an Ada-knowledgeable Eclipse plug-in
  - GNATdashboard — a metric integration and management platform

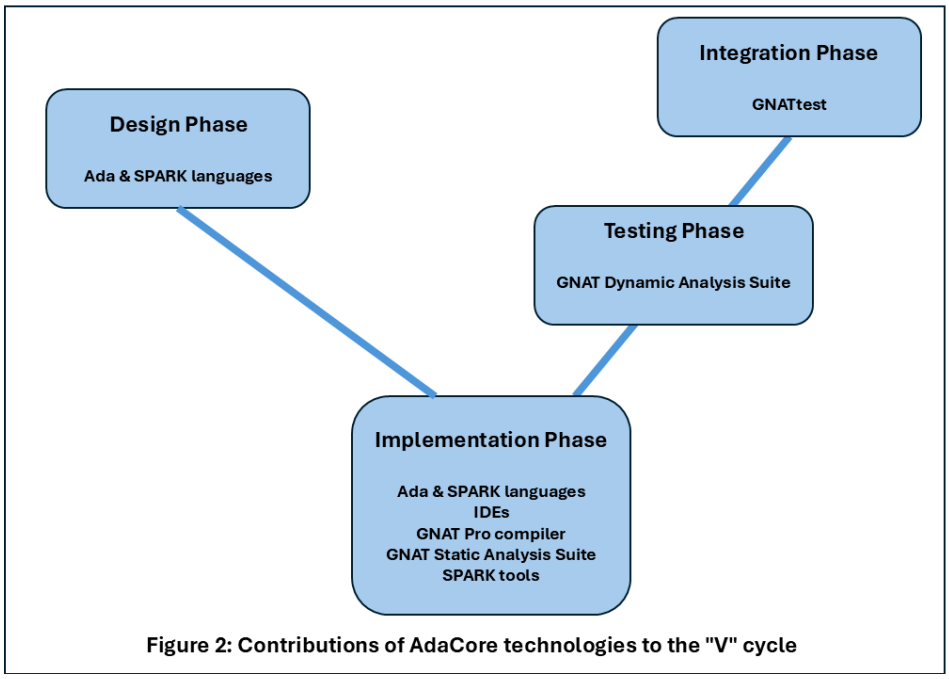

Fig. 5: Contributions of AdaCore technology to the "V" Cycle

CHAPTER

TWO

CENELEC EN 50128

142.1 Overview

EN 50128 governs software used in railway control and protection applications, i.e., systems that ensure the safe and efficient movement of trains. Examples include:

- *Automatic Train Protection (ATP)*, which ensures automatic braking to avoid collisions or overspeed;
- *Interlocking Systems*, which prevent conflicting train movements through tracks, signals, and switches;
- *Train Control Management Systems (TCMS)*, which coordinate control of subsystems (doors, brakes, traction);
- *Level Crossing Protection*, which manages gates and warnings at road-rail intersections; and
- *Centralized Traffic Control (CTC)*, which oversees train routing and dispatch across large regions.

The goal of the standard is to provide confidence that the software functions reliably and safely relative to its SIL. To this end it specifies requirements in areas including the following:

- Software development lifecycle processes;
- Verification and validation;
- Tools, techniques, and documentation;
- Risk mitigation measures; and
- Assessment of compliance with the standard.

More specifically, EN 50128 identifies the procedures and prerequisites (organization, independence and competencies management, quality management, V&V team, etc.) applicable to the development of programmable electronic systems used in railway control and protection applications. The standard therefore may apply to some software applications in the rail sector but not necessarily to all.

EN 50128 is used in both safety-related and non-safety-related applications and applies exclusively to software and its interaction with the whole system. (In light of its role in the certification of non-safety-related software, the standard introduces the Safety Integrity Level "Basic Integrity", which pertains to software that is not safety related.)

Although EN 50128 is targeted to the rail industry, it is not intrinsically domain specific. The standard is basically a specification of sound software engineering practices for long-lived large-scale high-assurance systems in general and could in principle be applied in other domains.

One of the distinctive points of EN 50128 is its requirement to justify the implementation of the resources. For this reason, it is said to be a "resources standard".

142.2 Structure of the standard

Fig. 6 illustrates the structure of EN 50128 (note that chapters in CENELEC standards are referred to as clauses, and individual sections and sub-sections within a chapter are sub-clauses).

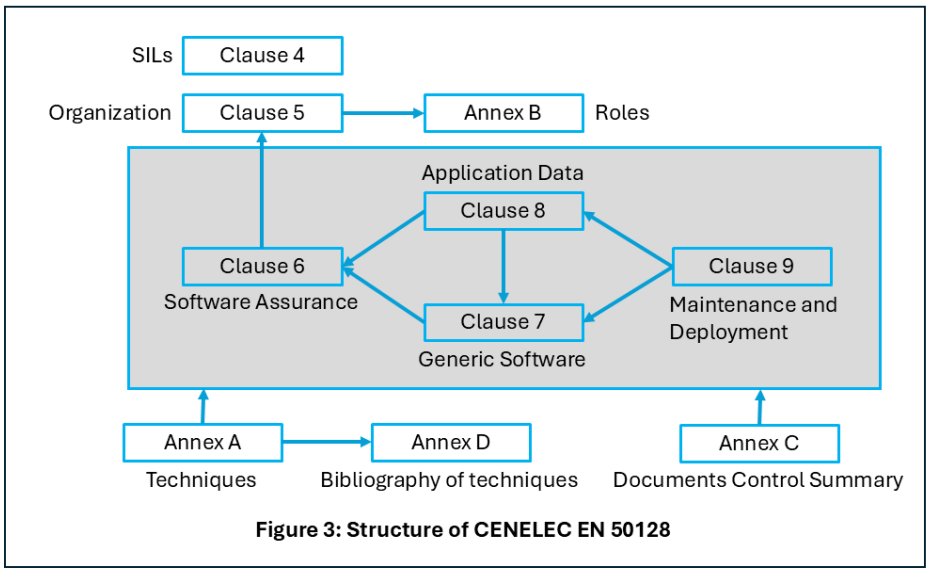

Fig. 6: Structure of CENELEC EN 50128

Clauses 1, 2, and 3 — *Scope*, *Normative references*, and *Terms, definitions and abbreviations*, respectively — provide context and basic information.

Clause 4, *Objectives, conformance and software safety integrity levels*, identifies the five Safety Integrity Levels and states the criterion for conformance to the standard:

> *To conform to this European standard it shall be shown that each of the requirements has been satisfied to the software safety integrity level defined and therefore the objective of the sub-clause in question has been met.*

This clause also specifies the role of normative Annex A in the selection of techniques and measures for satisfying the requirements, and the means for verifying compliance (inspection of the required documents, augmented when appropriate by other evidence such as auditing and the witnessing of tests).

Clauses 5 through 9 form the core of the standard, with sub-clauses providing the following content:

- *Objective*: the purpose of meeting the requirements specified in the sub-clause
- *Input documents* (if applicable)
- *Output documents* (if applicable)
- *Requirements*: Details on what the software supplier needs to do or provide. In some cases the requirements reference the tables in Annex A for specific techniques or measures to be used.

Clause 5, *Software management and organization*, covers three topics:

- Organization, roles and responsibilities (sub-clause 5.1);

- Personnel competence (sub-clause 5.2); and
- Lifecycle-related issues (sub-clause 5.3).

The standard does not dictate a specific lifecycle, but it cites the "V" approach as a recommendation, from the software specification to the overall software testing and integration, and also imposes some requirements. For example, the chosen lifecycle model needs to account for potential iterations between phases, and detailed documentation in the Software Quality Assurance Plan as specified in sub-clause 6.5 has to be supplied.

Clause 6, *Software assurance*, has the goal of achieving a software package with a minimum level of error and involves a variety of activities and technologies:

- Software testing (sub-clause 6.1);
- Software verification (sub-clause 6.2) — defined in sub-clause 3.1.48 as "confirmation, through the provision of objective evidence, that specified requirements have been fulfilled";
- Software validation (sub-clause 6.3) — defined in sub-clause 3.1.46 as "confirmation, through the provision of objective evidence, that the requirements for a specific intended use or application have been fulfilled";
- Software assessment (sub-clause 6.4);
- Software quality assurance (sub-clause 6.5);
- Modification and change control (sub-clause 6.6); and
- Support tools and languages (sub-clause 6.7) — see *Tool qualification* (page 2680) below.

As shown in[649], for software applications the assessment process involves demonstrating that the software application achieves its associated safety objectives.

EN 50128 makes a clear separation between the application software, referred to as the *generic software* (Clause 7), and the data or algorithms that are used to configure the generic software (Clause 8).

Clause 7, *Generic software development*, has the following sub-clauses:

- Lifecycle and documentation for generic software (sub-clause 7.1);
- Software requirements (sub-clause 7.2);
- Architecture and Design (sub-clause 7.3);
- Component design (sub-clause 7.4);
- Component implementation and testing (sub-clause 7.5);
- Integration (sub-clause 7.6); and
- Overall Software Testing / Final Validation (sub-clause 7.7).

Clause 8, *Development of application data or algorithms: systems configured by application data or algorithms*, ensures that the configuration parameters are verified and validated with the same degree of assurance, based on the relevant SIL, as is needed for the generic software that they configure.

An important part of the standard is Clause 9, *Software deployment and maintenance*. As stated in sub-clauses 9.1.1 and 9.2.1, the objectives of this clause are, respectively:

> *To ensure that the software performs as required, preserving the required software integrity level when it is deployed in the final environment of the application.*

and

[649] Jean-Louis Boulanger and Walter Schön. Assessment of Safety Railway Application. In *ESREL 2007 - the 18th European Safety and Reliability Conference*. 2007.

> *To ensure that the software performs as required, preserving the required software integrity level and dependability when making corrections, enhancements or adaptations to the software itself.*

Annex A (normative), *Criteria for the Selection of Techniques and Measures*, contains a set of tables that correlate the artifacts and practices (documentation, techniques, and measures) specified elsewhere in the standard, with an indication of whether, and how strongly, they are recommended based on the software's SIL:

- **M**: Mandatory. Must be used
- **HR**: Highly Recommended. If not used, need to explain rationale for using alternative technique
- **R**: Recommended
- **--**: No recommendation either for or against usage
- **NR**: Not recommended. If used, need to explain rationale for decision

Annex A consists of two sub-clauses:

- *Clauses tables (A.1)*; the table headings identify the sub-clause(s) containing the relevant requirements:
  - Table A.1 – Lifecycle Issues and Documentation (5.3)
  - Table A.2 – Software Requirements Specification (7.2)
  - Table A.3 – Software Architecture (7.3)
  - Table A.4 – Software Design and Implementation (7.4)
  - Table A.5 – Verification and Testing (6.2 and 7.3)
  - Table A.6 – Integration (7.6)
  - Table A.7 – Overall Software Testing (6.2 and 7.7)
  - Table A.8 – Software Analysis Techniques (6.3)
  - Table A.9 – Software Quality Assurance (6.5)
  - Table A.10 – Software Maintenance (9.2)
  - Table A.11 – Data Preparation Techniques (8.4)
- *Detailed tables (A.2)*; these are lower-level tables that expand on certain entries in the Clauses tables:
  - Table A.12 – Coding Standards
  - Table A.13 – Dynamic Analysis and Testing
  - Table A.14 – Functional/Black Box Test
  - Table A.15 – Textual Programming Languages
  - Table A.16 – Diagrammatic Languages for Application Algorithms
  - Table A.17 – Modeling
  - Table A.18 – Performance Testing
  - Table A.19 – Static Analysis
  - Table A.20 – Components
  - Table A.21 – Test Coverage for Code
  - Table A.22 – Object Oriented Software Architecture
  - Table A.23 – Object Oriented Detailed Design

As an example, Table A.4 contains a row for the programming language(s) selection:

Technique/Measure	Ref	Basic Integrity	SIL 1	SIL 2	SIL 3	SIL 4
...	...	...	...	...	...	...
10 Programming Language	Table A.15	R	HR	HR	HR	HR
...	...	...	...	...	...	...

Table A.15 contains a row for Ada:

Technique/Measure	Ref	Basic Integrity	SIL 1	SIL 2	SIL 3	SIL 4
ADA	D.54	R	HR	HR	HR	HR
...	...	...	...	...	...	...

Sub-clause D.54 (*Suitable Programming languages*) notes the features that a suitable language should have (e.g., run-time array bound checking), and features that it should encourage (e.g., definition of variable sub-ranges). On the other side, D.54 also lists features that should be avoided because they complicate verification (e.g., implicit variable initialization).

The entries in Tables A.4 and A.15 show that Ada is a Highly Recommended language at SIL 1 through SIL 4 and a Recommended language at the Basic Integrity level. Features that should be avoided can be detected and prevented by using AdaCore's GNATcheck tool in CodeSonar for Ada; see *CodeSonar for Ada* (page 2692).

Annex B (normative), *Key software roles and responsibilities*, consists of ten tables detailing the responsibilities and key competencies for the various roles specified in the standard: Requirements Manager, Designer, Implementor, Tester, Verifier, Integrator, Validator, Assessor, Project Manager, and Configuration Manager.

Annex C (informative), *Documents Control Summary*, provides a table that lists, for each project phase, its output documents and, for each document, the responsible author and reviewer(s). The lifecycle phases and their associated document count are:

- *Planning:* 5 documents
- *Software requirements:* 3 documents
- *Architecture and design:* 6 documents
- *Component design:* 3 documents
- *Component implementation and testing:* 3 documents
- *Integration:* 3 documents
- *Overall software testing / Final validation:* 4 documents
- *Systems configured by application data/algorithms:* 8 documents
- *Software deployment:* 5 documents
- *Software maintenance:* 4 documents
- *Software assessment:* 2 documents

Annex D (informative), *Bibliography of techniques*, details the aim and description for seventy-one specific software engineering practices. These are applicable at various lifecycle phases; for example:

- Coding Standards and Style Guide (sub-clause D.15) and Language Subset (sub-clause D.35) at the design and implementation phase,

- Formal Methods and Formal Proof (sub-clauses D.28 and D.29) at the implementation and verification phases, and
- Equivalence Classes and Input Partition Testing (sub-clause D.18) at the testing phase.

Annex ZZ (Informative), *Relationship between this European standard and the essential requirements of EU Directive 2016/797/EU [2016 OJ L138] aimed to be covered* was introduced in EN 50128/A1. It contains a table showing the relationship noted in the Annex title.

142.3 Tool qualification

An earlier edition of the standard, EN 50128:2001, introduced a requirement that the compilers employed for a project be purpose-certified, but did not give a clear indication of what precisely was expected. Clause 6.7 in the 2011 revision formalizes this concept, which will be referred to here as "tool qualification", and provides details on what needs to be performed and/or supplied. (The standard does not use a specific term for this process, but the "tool qualification" terminology from the airborne software standards DO - 178C/ED - 12C[650] and DO - 330/ED - 215[651] is appropriate.)

142.3.1 Tool classes

Tool qualification is based on the recognition that different tools need different levels of confidence in their reliability, based on how a tool error affects the application software. This is formalized in the concept of a "tool class". As stated in sub-clause 6.7.1:

> *The objective is to provide evidence that potential failures of tools do not adversely affect the integrated toolset output in a safety related manner that is undetected by technical and/or organisational measures outside the tool. To this end, software tools are categorised into three classes namely, T1, T2 & T3 respectively.*

- **T1** is reserved for tools that affect neither the verification of the software nor the final executable file.
- **T2** applies to tools where a fault could lead to an error in the results of the verification or validation. Examples include tools used for verifying compliance with a coding standard, generating quantified metrics, performing static analysis of the source code, managing and executing tests, etc.
- **T3** applies to tools where a fault could have an impact on (and, for example, introduce errors into) the final executable software. This class includes compilers, code generators, etc.

Sub-clause 6.7 of EN 50128 defines a set of recommendations for each tool class; these affect the content of the tool qualification report. The standard identifies twelve requirements (numbered from 6.7.4.1 to 6.7.4.12) concerning tool qualification. Requirement 6.7.4.12 is a mapping from each tool class to the applicable sub-clauses in the standard. It is shown here in the table below, which augments the version in the standard by also specifying the lifecycle phase that is relevant for each sub-clause. The steps shown indicate the requirements to be met and reflect the additional effort needed as the tool level increases; for further information, please see[652], Chapter 9.

Tool class	Applicable sub-clause(s)	Lifecycle phase
T1	6.7.4.1	Tool identification
T2	6.7.4.1	Tool identification
	6.7.4.2	Tool justification
	6.7.4.3	Tool specification/manual
	6.7.4.10, 6.7.4.11	Tool version management
T3	6.7.4.1	Tool identification

142.3.2 AdaCore tool qualification support

As will be explained below, AdaCore supports EN 50128 compliance through tools qualified for several purposes:

- Static and dynamic analysis;
- Code verification including formal proof; and
- Compilation with traceability and reproducibility guarantees.

These capabilities reduce certification risk while improving code quality and lifecycle confidence.

AdaCore's qualification packages contain the information required by EN 50128, such as documentation, history, infrastructure, user references, recommended usage, validation strategy, configuration management and change tracking.

Furthermore, tools can be provided through a subscription service known as "sustained branches" (see *Sustained Branches* (page 2689)). In this mode, a specific version of the tools can be put into special maintenance, where AdaCore can investigate known problems and provide repairs or work-arounds for potential issues on these branches without unrelated updates that may risk regressions.

AdaCore's decades-long experience in software certification for embedded and safety-critical domains, including rail and avionics, ensures that customers have access to:

- Qualification material for EN 50128 and/or DO - 330/ED - 215 tool assessment;
- A formally verifiable language (SPARK) for high-integrity use cases; and
- Lifecycle support aligned with the needs of long-term platform deployments

CHAPTER

THREE

ADACORE TOOLS AND TECHNOLOGIES OVERVIEW

143.1 Ada

143.1.1 Background

Ada is a modern programming language designed for large, long-lived applications — and embedded systems in particular — where reliability, maintainability, and efficiency are essential. It was originally developed in the early 1980s (this version is generally known as Ada 83) by a team led by Jean Ichbiah at CII-Honeywell-Bull in France. The language was revised and enhanced in an upward compatible fashion in the early 1990s, under the leadership of Tucker Taft from Intermetrics in the U.S.

The resulting language, Ada 95, was the first internationally standardized (ISO) object-oriented language. Under the auspices of ISO, a further (minor) revision was completed as an amendment to the standard; this version of the language is known as Ada 2005. Additional features (including support for contract-based programming in the form of subprogram pre- and postconditions and type invariants) were added in the Ada 2012 version of the language standard, and a number of features to increase the language's expressiveness were introduced in Ada 2022 (see[653],[654],[655],[656] for information about Ada).

The name "Ada" is not an acronym; it was chosen in honor of Augusta Ada Lovelace (1815-1852), a mathematician who is regarded as the world's first programmer because of her work with Charles Babbage. She was also the daughter of the poet Lord Byron.

The Ada language is seeing significant usage worldwide in high-integrity / safety-critical / high-security domains including railway systems, commercial and military aircraft avionics, air traffic control, and medical devices.

With its embodiment of modern software engineering principles, Ada is an excellent teaching language for both introductory and advanced computer science courses, and it has been the subject of significant university research especially in the area of real-time technologies. The so-called Ravenscar Profile — a subset of the language's concurrency features with deterministic semantics — broke new ground in supporting the use of concurrent programming in high assurance software.

AdaCore has a long history and close connection with the Ada programming language. Company members worked on the original Ada 83 design and review and played key roles in the Ada 95 project as well as the subsequent revisions. AdaCore's initial GNAT compiler was essential to the growth of Ada 95; it was delivered at the time of the language's standard-

ization, thus guaranteeing that users would have a quality implementation for transitioning to Ada 95 from Ada 83 or other languages.

143.1.2 Language Overview

Ada is multi-faceted. From one perspective it is a classical stack-based general-purpose language, not tied to any specific development methodology. It has a simple syntax, structured control statements, flexible data composition facilities, strong type checking, traditional features for code modularization (*subprograms*), and a mechanism for detecting and responding to exceptional run-time conditions (*exception handling*). But it also includes much more:

Scalar Ranges

Unlike languages based on C syntax (such as C++, Java, and C#), Ada allows the programmer to simply and explicitly specify the range of values that are permitted for variables of scalar types (integer, floating-point, fixed-point, and enumeration types). The attempted assignment of an out-of-range value causes a run-time error. The ability to specify range constraints makes programmer intent explicit and makes it easier to detect a major source of coding and user input errors. It also provides useful information to static analysis tools and facilitates automated proofs of program properties.

Here's an example of an integer scalar range:

```
declare
   Score : Integer range 1..100;
   N     : Integer;
begin
   ... -- Code that assigns a value to N
   Score := N;
   -- A run-time check verifies that N is within the range 1..100
   -- If this check fails, the Constraint_Error exception is raised
end;
```

Contract-Based Programming

A feature introduced in Ada 2012 allows extending a subprogram specification or a type/subtype declaration with a contract (a Boolean assertion). Subprogram contracts take the form of preconditions and postconditions, type contracts are used for invariants, and subtype contracts provide generalized constraints (predicates). Through contracts the developer can formalize the intended behavior of the application, and can verify this behavior by testing, static analysis or formal proof.

Here's a skeletal example that illustrates contract-based programming; a `Table` object is a fixed-length container for distinct **`Float`** values.

```
package Table_Pkg is
   type Table is private;  -- Encapsulated type

   procedure Insert (T : in out Table; Item: in Float)
     with Pre  => not Is_Full(T) and not Contains(T, Item),
          Post => Contains(T, Item);

   procedure Remove (T : in out Table; Item: out Float);
     with Pre  => Contains(T, Item),
          Post => not Contains(T, Item);

   function Is_Full  (T : in Table) return Boolean;
   function Contains (T : in Table; Item: in Float) return Boolean;
```

(continues on next page)

(continued from previous page)

```
   ...
private
   ... -- Full declaration of type Table
end Table_Pkg;

package body Table_Pkg is
   ... -- Implementation of Insert, Remove, Is_Full, and Contains
end Table_Pkg;
```

A compiler option controls whether the pre- and postconditions are checked at run time. If checks are enabled, any pre- or postcondition failure — i.e., the contract's Boolean expression evaluating to **False** — raises the `Assertion_Error` exception.

Programming in the large

The original Ada 83 design introduced the package construct, a feature that supports encapsulation (*information hiding*) and modularization, and which allows the developer to control the namespace that is accessible within a given compilation unit. Ada 95 introduced the concept of *child units*, adding considerable flexibility and easing the design of very large systems. Ada 2005 extended the language's modularization facilities by allowing certain kinds of mutual references between package specifications, thus making it easier to interface with languages such as Java.

Generic Templates

A key to reusable components is a mechanism for parameterizing modules with respect to data types and other program entities, for example a stack package for an arbitrary element type. Ada meets this requirement through a facility known as *generics*; since the parameterization is done at compile time, run-time performance is not penalized.

Object-Oriented Programming (OOP)

Ada 83 was object-based, allowing the partitioning of a system into modules corresponding to abstract data types or abstract objects. Full OOP support was not provided since, first, it seemed not to be required in the real-time domain that was Ada's primary target, and, second, the apparent need for automatic garbage collection in an Object-Oriented language would have interfered with predictable and efficient performance.

However, large real-time systems often have components such as GUIs that do not have real-time constraints and that could be most effectively developed using OOP features. In part for this reason, Ada 95 supplies comprehensive support for OOP, through its *tagged type* facility: classes, polymorphism, inheritance, and dynamic binding. Ada 95 does not require automatic garbage collection but rather supplies definitional features allowing the developer to supply type-specific storage reclamation operations (*finalization*). Ada 2005 brought additional OOP features including Java-like interfaces and traditional `obj.op(...)` operation invocation notation.

Ada is methodologically neutral and does not impose a distributed overhead for OOP. If an application does not need OOP, then the OOP features do not have to be used, and there is no run-time penalty. SeePage 2683, 655 or[657] for more details.

[657] *High-Integrity Object-Oriented Programming in Ada, Version 1.4*. AdaCore, October 2016. URL: https://www.adacore.com/knowledge/technical-papers/high-integrity-oop-in-ada/.

Concurrent Programming

Ada supplies a structured, high-level facility for concurrency. The unit of concurrency is a program entity known as a *task*. Tasks can communicate implicitly via shared data or explicitly via a synchronous control mechanism known as the rendezvous. A shared data item can be defined abstractly as a *protected object* (a feature introduced in Ada 95), with operations executed under mutual exclusion when invoked from multiple tasks. Protected objects provide the functionality of semaphores and condition variables but more clearly and reliably (e.g., avoiding subtle race conditions).

Ada supports asynchronous task interactions for timeouts, software event notifications, and task termination. Such asynchronous behavior is deferred during certain operations, to prevent the possibility of leaving shared data in an inconsistent state. Mechanisms designed to help take advantage of multi-core architectures were introduced in Ada 2012.

Systems Programming

Both in the *core* language and the Systems Programming Annex, Ada supplies the necessary features for hardware-specific processing. For example, the programmer can specify the bit layout for fields in a record, define alignment and size properties, place data at specific machine addresses, and express specialized code sequences in assembly language. Interrupt handlers can be written in Ada, using the protected type facility.

Real-Time Programming

Ada's tasking facility and the Real-Time Systems Annex support common idioms such as periodic or event-driven tasks, with features that can help avoid unbounded priority inversions. A protected object locking policy is defined that uses priority ceilings; this has an especially efficient implementation in Ada (mutexes are not required) since protected operations are not allowed to block. Ada 95 defined a task dispatching policy that basically requires tasks to run until blocked or preempted. Subsequent versions of the language standard introduced several other policies, such as Earliest Deadline First.

High-Integrity Systems

With its emphasis on sound software engineering principles, Ada supports the development of high-integrity applications, including those that need to be certified against safety standards such EN 50128 for rail systems, DO - 178C/ED - 12C[658] for avionics, and security standards such as the Common Criteria[659]. Key to Ada's support for high-assurance software is the language's memory safety; this is illustrated by a number of features, including:

- *Strong typing*

  Data intended for one purpose will not be accessed via inappropriate operations; errors such as treating pointers as integers (or vice versa) are prevented.

- *Array bounds checking*

  A run-time check guarantees that an array index is within the bounds of the array. This prevents buffer overflow vulnerabilities that are common in C and C++. In many cases a compiler optimization can detect statically that the index is within bounds and thus eliminate any run-time code for the check.

- *Prevention of null pointer dereferences*

  As with array bounds, pointer dereferences are checked to make sure that the pointer is not null. Again, such checks can often be optimized out.

[658] *DO-178C/ED-12C: Software Considerations in Airborne Systems and Equipment Certification*. RTCA and EUROCAE, December 2011.
[659] *Common Criteria for Information Technology Security Evaluation (ISO/IEC 15408)*. Common Criteria Development Board, 2022. URL: https://www.commoncriteriaportal.org/.

- *Prevention of dangling references*

  A scope accessibility check ensures that a pointer cannot reference an object on the stack after exit/return from the scope (block or subprogram) in which the object is declared. Such checks are generally static, with no run-time overhead.

However, the full language may be inappropriate in a safety-critical application, since the generality and flexibility could interfere with traceability / certification requirements. Ada addresses this issue by supplying a compiler directive, `pragma Restrictions`, that allows constraining the language features to a well-defined subset (for example, excluding dynamic OOP facilities).

The evolution of Ada has seen the continued increase in support for safety-critical and high-security applications. Ada 2005 standardized the Ravenscar Profile, a collection of concurrency features that are powerful enough for real-time programming but simple enough to make certification and formal analysis practical.

Ada 2012 introduced contract-based programming facilities, allowing the programmer to specify preconditions and/or postconditions for subprograms, and invariants for encapsulated (private) types. These can serve both for run-time checking and as input to static analysis tools.

The most recent version of the standard, Ada 2022, has added several contract-based programming constructs inspired by SPARK (`Contract_Cases`, `Global`, and `Depends` aspects) and, more generally, has enhanced the language's expressiveness. For example, Ada 2022 has introduced some new syntax in its concurrency support and has defined the Jorvik tasking profile, which is more inclusive than Ravenscar.

Summary

In brief, Ada is an internationally standardized language combining object-oriented programming features, well-engineered concurrency facilities, real-time support, and built-in reliability through both compile-time and run-time checks. As such it is an appropriate language for addressing the real issues facing software developers today. Ada has a long and successful history and is used throughout a number of major industries to design software that protects life and property.

143.2 SPARK

SPARK is a software development technology (programming language and verification toolset) specifically designed for engineering ultra-low defect level applications, for example where safety and/or security are key requirements. SPARK Pro is AdaCore's commercial-grade offering of the SPARK technology. The main component in the toolset is GNATprove, which performs formal verification on SPARK code.

SPARK has an extensive industrial track record. Since its inception in the late 1980s it has been used worldwide in a range of industrial applications such as railway signaling, civil and military avionics, air traffic management / control, cryptographic software, and cross-domain solutions.

The SPARK language has been stable over the years, with periodic enhancements. The 2014 version of SPARK represented a major revision[660],[661]), incorporating contract-based programming syntax from Ada 2012, and subsequent upgrades included support for pointers (access types) based on the Rust ownership model.

[660] John W. McCormick and Peter C. Chapin. *Building High Integrity Applications with SPARK*. Cambridge University Press, 2015.

[661] *SPARK Reference Manual, Release 2020*. AdaCore and Altran, 2020. URL: https://www.adacore.com/uploads/techPapers/spark_rm_community_2020.pdf.

143.2.1 Flexibility

SPARK offers the flexibility of configuring the language on a per-project basis. Restrictions can be fine-tuned based on the relevant coding standards or run-time environments. SPARK code can easily be combined with full Ada code or with C, so that new systems can be built on and reuse legacy codebases.

143.2.2 Powerful Static Verification

The SPARK language supports a wide range of static verification techniques. At one end of the spectrum is basic data and control flow analysis, i.e., exhaustive detection of errors such as attempted reads of uninitialized variables, and ineffective assignments (where a variable is assigned a value that is never read). For more critical applications, dependency contracts can constrain the information flow allowed in an application. Violations of these contracts — potentially representing violations of safety or security policies — can then be detected even before the code is compiled.

In addition, the language supports mathematical proof and can thus provide high confidence that the software meets a range of assurance requirements: from the absence of run-time errors (*AORTE*), to the enforcement of safety or security properties, to compliance with a formal specification of the program's required behavior.

143.2.3 Ease of Adoption

User experience has shown that the language and the SPARK Pro toolset do not require a steep learning curve. Training material such as AdaCore's online AdaLearn course for SPARK[662] can quickly bring developers up to speed; users are assumed to be experts in their own application domain such as railway software and do not need to be familiar with formal methods or the proof technology implemented by the toolset. In effect, SPARK Pro is an advanced static analysis tool that will detect many logic errors very early in the software life cycle. It can be smoothly integrated into an organization's existing development and verification methodology and infrastructure.

SPARK uses the standard Ada 2012 contract syntax, which both simplifies the learning process and also allows new paradigms of software verification. Programmers familiar with writing executable contracts for run-time assertion checking can use the same approach but with additional flexibility: the contracts can be verified either dynamically through classical run-time testing methods or statically (i.e., pre-compilation and pre-test) using automated tools.

143.2.4 Hybrid Verification

SPARK supports *hybrid verification*, which combines testing and formal proofs. As an example, an existing project in Ada and C can adopt SPARK to implement new functionality for critical components. The SPARK units can be analyzed statically to achieve the desired level of verification, with testing performed at the interfaces between the SPARK units and the modules in the other languages.

143.2.5 Reduced Cost and Improved Efficiency of Executable Object Code Verification

Software verification typically involves extensive testing, including unit tests and integration tests. Traditional testing methodologies are a major contributor to the high delivery costs for safety-critical software. Furthermore, they may fail to detect errors. SPARK addresses this issue by allowing automated proof to be used to demonstrate functional correctness at the subprogram level, either in combination with or as a replacement for unit

[662] AdaCore. Online training for Ada and SPARK. URL: https://learn.adacore.com/.

testing. In the high proportion of cases where proofs can be discharged automatically, the cost of writing unit tests is completely avoided. Moreover, verification by proofs covers all execution conditions and not just a sample.

143.3 GNAT Pro Assurance

143.3.1 Sustained Branches

GNAT Pro Assurance is a specialized version of the GNAT Pro development environment, available for any of the products in the GNAT Pro family: GNAT Pro for Ada, GNAT Pro for C, GNAT Pro for C++, and GNAT Pro for Rust. It is targeted to projects requiring customized support, including bug fixes and *known problems* analyses, on a specific version of the toolchain. This service is especially suitable for applications with long maintenance cycles or certification requirements, since critical updates to the compiler or other product components may become necessary years after the initial release. Such customized maintenance of a specific version of the product is known as a *sustained branch*.

A project on a sustained branch can monitor relevant known problems, analyze their impact and, if needed, update to a newer version of the product on the same development branch (i.e., not incorporating changes introduced in later versions of the product).

Sustained branches are a practical solution to the problem of ensuring toolchain stability while allowing flexibility in case an upgrade is needed to correct a critical problem.

143.3.2 Language and Tool Support

GNAT Pro Assurance for Ada supports all versions of the Ada language standard as well as multiple versions of C (C89, C99, and C11). It provides an Integrated Development Environment (see *Integrated Development Environments (IDEs)* (page 2695)), a comprehensive toolsuite including a visual debugger, and an extensive set of libraries and bindings. Details on the GNAT Pro for Ada toolchain may be found in[663]. AdaCore's GNAT project facility, based on a multi-language builder for systems organized into subsystems and libraries, is documented in[664].

143.3.3 Configurable Run-Time Libraries

Two specific GNAT-defined run-time libraries have been designed with certification in mind and are known as the Certifiable Profiles (see[665]):

- *Light Profile*
- *Light-Tasking Profile*

The Light Profile provides a flexible Ada subset that is supported by a certifiable Ada run-time library. Depending on application requirements, this profile can be further restricted through the `Restrictions` pragma, with the application only including run-time code that is used by the application.

These run-time libraries can also be customized directly to suit certification requirements: unneeded packages can be removed to allow for self-certification of the runtime, while the `-nostdlib` linker switch can be used to prevent the use of the runtime. Even when the run-time library is suppressed, some run-time sources are still required to provide compile-time definitions. While this code produces no object code, the certification protocol may still require tests to ensure correct access to these definitions.

[663] AdaCore. GNAT User's Guide for Native Platforms. URL: https://docs.adacore.com/live/wave/gnat_ugn/html/gnat_ugn/gnat_ugn.html.
[664] AdaCore. GPRbuild and GPR Companion Tools User's Guide. URL: https://docs.adacore.com/gprbuild-docs/html/gprbuild_ug.html.
[665] AdaCore. GNAT User's Guide Supplement for Cross Platforms. URL: https://docs.adacore.com/live/wave/gnat_ugx/html/gnat_ugx/gnat_ugx.html.

The Light-Tasking Profile expands the Light Profile to include Ravenscar tasking support, allowing developers to use concurrency in their certification applications.

Although limited in terms of dynamic Ada semantics, all Certifiable Profiles fully support static Ada constructs such as private types, generic templates, and child units. Some dynamic semantics are also supported. For example, these profiles allow the use of tagged types (at library level) and other Object-Oriented Programming features, including dynamic dispatching. The general use of dynamic dispatching at the application level can be prevented through pragma `Restrictions`.

A traditional problem with predefined profiles is their inflexibility: if a feature outside a given profile is needed, then it is the developer's responsibility to address the certification issues deriving from its use. GNAT Pro Assurance accommodates this need by allowing the developer to define a profile for the specific set of features that are used. Typically this will be for features with run-time libraries that require associated certification materials. Thus the program will have a tailored run-time library supporting only those features that have been specified.

More generally, the configurable run-time capability allows specifying support for Ada's dynamic features in an à la carte fashion ranging from none at all to full Ada. The units included in the executable may be either a subset of the standard libraries provided with GNAT Pro, or specially tailored to the application. This latter capability is useful, for example, if one of the predefined profiles implements almost all the dynamic functionality needed in an existing system that has to meet new safety-critical requirements, and where the costs of adapting the application without the additional run-time support are considered prohibitive.

143.3.4 Full Implementation of Ada Standards

GNAT Pro provides a complete implementation of the Ada language from Ada 83 to Ada 2012, and support for selected features from Ada 2022. Developers of safety-critical and high-security systems can thus take advantage of features such as contract-based programming, which effectively embed requirements in the source program text and simplify verification.

143.3.5 Source to Object Traceability

A compiler option can limit the use of language constructs that generate object code that is not directly traceable to the source code. As an add-on service, AdaCore can perform an analysis that demonstrates this traceability and justifies any remaining cases of non-traceable code.

143.3.6 Safety-Critical Support and Expertise

At the heart of every AdaCore subscription are the support services that AdaCore provides to its customers. AdaCore staff are recognized experts on the Ada language, software certification standards in several domains, compilation technologies, and static and dynamic verification. They have extensive experience in supporting customers in railway, avionics, space, energy, air traffic management/control, automotive, and military projects. Every AdaCore product comes with front-line support provided directly by these experts, who are also the developers of the technology. This ensures that customers' questions (requests for guidance on feature usage, suggestions for technology enhancements, or defect reports) are handled efficiently and effectively.

Beyond this bundled support, AdaCore also provides Ada language and tool training as well as on-site consulting on topics such as how to best deploy the technology, and assistance on start-up issues. On-demand tool development and ports to new platforms are also available.

143.3.7 Libadalang

Libadalang is a library included with GNAT Pro that gives applications access to the complete syntactic and semantic structure of an Ada compilation unit. This library is typically used by tools that need to perform some sort of static analysis on an Ada program.

AdaCore can assist customers in developing libadalang-based tools to meet their specific needs, as well as develop such tools upon request.

Typical libadalang applications include:

- Static analysis (property verification)
- Code instrumentation
- Design and document generation tools
- Metric testing or timing tools
- Dependency tree analysis tools
- Type dictionary generators
- Coding standard enforcement tools
- Language translators (e.g., to CORBA IDL)
- Quality assessment tools
- Source browsers and formatters
- Syntax directed editors

143.3.8 GNATstack

Included with GNAT Pro is GNATstack, a static analysis tool that enables an Ada/C software developer to accurately predict the maximum size of the memory stack required for program execution.

GNATstack statically predicts the maximum stack space required by each task in an application. The computed bounds can be used to ensure that sufficient space is reserved, thus guaranteeing safe execution with respect to stack usage. The tool uses a conservative analysis to deal with complexities such as subprogram recursion, while avoiding unnecessarily pessimistic estimates.

This static stack analysis tool exploits data generated by the compiler to compute worst-case stack requirements. It performs per-subprogram stack usage computation combined with control flow analysis.

GNATstack can analyze object-oriented applications, automatically determining maximum stack usage on code that uses dynamic dispatching in Ada. A dispatching call challenges static analysis because the identity of the subprogram being invoked is not known until run time. GNATstack solves this problem by statically determining the subset of potential targets (primitive operations) for every dispatching call. This significantly reduces the analysis effort and yields precise stack usage bounds on complex Ada code.

GNATstack's analysis is based on information known at compile time. When the tool indicates that the result is accurate, the computed bound can never be exceeded.

On the other hand, there may be cases in which the results will not be accurate (the tool will report such situations) because of some missing information (such as the maximum depth of subprogram recursion, indirect calls, etc.). The user can assist the tool by specifying missing call graph and stack usage information.

GNATstack's main output is the worst-case stack usage for every entry point, together with the paths that result in these stack sizes. The list of entry points can be automatically computed (all the tasks, including the environment task) or can be specified by the user (a list of entry points or all the subprograms matching a given regular expression).

GNATstack can also detect and display a list of potential problems when computing stack requirements:

- Indirect (including dispatching) calls. The tool will indicate the number of indirect calls made from any subprogram.
- External calls. The tool displays all the subprograms that are reachable from any entry point for which there is no stack or call graph information.
- Unbounded frames. The tool displays all the subprograms that are reachable from any entry point with an unbounded stack requirement. The required stack size depends on the arguments passed to the subprogram. For example:

```
procedure P(N : Integer) is
   S : String (1..N);
begin
   ...
end P;
```

- Cycles. The tool can detect all the cycles (i.e., potential recursion) in the call graph.

GNATstack allows the user to supply a text file with the missing information, such as the potential targets for indirect calls, the stack requirements for external calls, and the maximal size for unbounded frames.

143.4 CodeSonar for Ada

143.4.1 Defects and Vulnerability Analyzer

CodeSonar for Ada features an Ada source code analyzer that detects run-time and logic errors. It assesses potential bugs and vulnerabilities before program execution, serving as an automated peer reviewer, helping to find errors easily at any stage of the development life-cycle. It helps improve code quality and makes it easier to perform safety and/or security analysis.

The defects and vulnerability analyzer can detect several of the "Top 25 Most Dangerous Software Errors" in the Common Weakness Enumeration. It is a stand-alone tool that runs on Windows and Linux platforms and may be used with any standard Ada compiler or fully integrated into the GNAT Pro development environment.

143.4.2 GNATmetric

The GNATmetric tool analyzes source code to calculate a set of commonly used industry metrics, thus allowing developers to estimate the size and better understand the structure of the source code. This information also facilitates satisfying the requirements of certain software development frameworks.

143.4.3 GNATcheck

GNATcheck is a coding standard verification tool that is extensible and rule-based. It allows developers to completely define a project-specific coding standard as a set of rules, for example a subset of permitted language features and/or code formatting and style conventions. It verifies a program's conformance with the resulting rules and thereby facilitates demonstration of a system's compliance with a certification standard's requirements on language subsetting.

GNATcheck provides:

- An integrated "Ada Restrictions" mechanism for banning specific features from an application. This can be used to restrict features such as tasking, exceptions, dynamic allocation, fixed- or floating point, input/output, and unchecked conversions.

- Restrictions specific to GNAT Pro, such as banning features that result in the generation of implicit loops or conditionals in the object code, or in the generation of elaboration code.
- Additional Ada semantic rules resulting from customer input, such as ordering of parameters, normalized naming of entities, and subprograms with multiple returns.
- An easy-to-use interface for creating and using a complete coding standard.
- Generation of project-wide reports, including evidence of the level of compliance with a given coding standard.
- Over 30 compile-time warnings from GNAT Pro that detect typical error situations, such as local variables being used before being initialized, incorrect assumptions about array lower bounds, infinite recursion, incorrect data alignment, and accidental hiding of names.
- Style checks that allow developers to control indentation, casing, comment style, and nesting level.

AdaCore's GNATformat tool[666], which formats Ada source code according to the GNAT coding style[667], can help avoid having code that violates GNATcheck rules. GNATformat is included in the GNAT Pro for Ada toolchain.

GNATcheck comes with a query language (LKQL, for Language Kit Query Language) that lets developers define their own checks for any in-house rules that need to be followed. GNATcheck can thus be customized to meet an organization's specific requirements, processes and procedures.

143.5 GNAT Dynamic Analysis Suite (GNAT DAS)

143.5.1 GNATtest

The GNATtest tool helps create and maintain a complete unit testing infrastructure for complex projects. It captures the simple idea that each public subprogram (these are known as *visible* subprograms in Ada) should have at least one corresponding unit test. GNATtest takes a project file as input, and produces two outputs:

- The complete harnessing code for executing all the unit tests under consideration. This code is generated completely automatically.
- A set of separate test stubs for each subprogram to be tested. These test stubs are to be completed by the user.

GNATtest handles Ada's Object-Oriented Programming features and can be used to help verify tagged type substitutability (the Liskov Substitution Principle) that can be used to demonstrate consistency of class hierarchies.

Testing a private subprogram is outside the scope of GNATtest but can be implemented by defining the relevant testing code in a private child of the package that declares the private subprogram. Additionally, hybrid verification can help (see *Hybrid Verification* (page 2688)): augmenting testing with the use of SPARK to formally prove relevant properties of the private subprogram.

143.5.2 GNATemulator

GNATemulator is an efficient and flexible tool that provides integrated, lightweight target emulation.

Based on the QEMU technology, a generic and open-source machine emulator and virtualizer, GNATemulator allows software developers to compile code directly for their target architecture and run it on their host platform, through an approach that translates from the target object code to native instructions on the host. This avoids the inconvenience and cost of managing an actual board, while offering an efficient testing environment compatible with the final hardware.

There are two basic types of emulators. The first can serve as a surrogate for the final hardware during development for a wide range of verification activities, particularly those that require time accuracy. However, they tend to be extremely costly, and are often very slow. The second, which includes GNATemulator, does not attempt to be a complete time-accurate target board simulator, and thus it cannot be used for all aspects of testing. But it does provide a very efficient and cost-effective way to execute the target code very early in the development and verification processes. GNATemulator thus offers a practical compromise between a native environment that lacks target emulation capability, and a cross configuration where the final target hardware might not be available soon enough or in sufficient quantity.

143.5.3 GNATcoverage

GNATcoverage is a code coverage analysis tool. Its results are computed from trace files that show which program constructs have been exercised by a given test campaign. With source code instrumentation, the tool produces these files by executing an alternative version of the program, built from source code instrumented to populate coverage-related data structures. Through an option to GNATcoverage, the user can specify the granularity of the analysis: statement coverage, decision coverage, or Modified Condition / Decision Coverage (MC/DC).

Source-based instrumentation brings several major benefits: efficiency of tool execution (much faster than alternative coverage strategies using binary traces and target emulation, especially on native platforms), compact-size source trace files independent of execution duration, and support for coverage of shared libraries.

143.5.4 GNATfuzz

GNATfuzz is a fuzzing tool; i.e., a tool that automatically and repeatedly executes tests and generates new test cases at a very high frequency to detect faulty behavior of the system under test. Such anomalous behavior is captured by monitoring the system for triggered exceptions, failing built-in assertions, and signals such as SIGSEGV.

Fuzz testing has proven to be an effective mechanism for finding corner-case vulnerabilities that traditional human-driven verification mechanisms, such as unit and integration testing, can miss. Since such vulnerabilities can often lead to malicious exploitations, fuzzing technology can help meet security verification requirements.

However, fuzz-testing campaigns are complex and time-consuming to construct, execute and monitor. GNATfuzz simplifies the process by analyzing a code base and identifying subprograms that can act as fuzz-test entry points. GNATfuzz then automates the creation of test harnesses suitable for fuzzing. In addition, GNATfuzz will automate the building, executing and analyzing of fuzz-testing campaigns.

GNATfuzz can serve a useful role as part of the software development and verification life cycle processes. For example, by detecting anomalous behavior such as data corruption due to task or interrupt conflicts, GNATfuzz can help prevent defects from being introduced into the source code.

143.5.5 TGen

TGen is an experimental run-time library / marshalling technology that can be used by GNATtest and/or GNATfuzz to automate the production of test cases for Ada code. It performs type-specific low-level processing to generate test vectors for subprogram parameters, such as uniform value distribution for scalar types and analogous strategies for unconstrained arrays and record discriminants. A command-line argument specifies the number of test values to be generated, and these can then be used as input to test cases created by GNATtest.

TGen can also be used with GNATfuzz, to help start a fuzz-testing campaign when the user supplies an initial set of test cases where some may contain invalid data. GNATfuzz will utilize coverage-driven fuzzer mutations coupled with TGen to convert invalid test cases into valid ones. TGen represents test data values compactly, removing a large amount of memory padding that would otherwise be present for alignment of data components. With its space-efficient representation, TGen significantly increases the probability of a successful mutation that results in a new valid test case.

143.6 GNAT Pro for Rust

The Rust language was designed for software that needs to meet stringent requirements for both assurance and performance: Rust is a memory-safe systems-programming language with software integrity guarantees (in both concurrent and sequential code) enforced by compile-time checks. The language is seeing growing use in domains such as automotive systems and is a viable choice for railway software.

AdaCore's GNAT Pro for Rust is a complete development environment for the Rust programming language, supporting both native builds and cross compilation to embedded targets. The product is not a fork of the Rust programming language or the Rust tools. Instead, GNAT Pro for Rust is a professionally supported build of a selected version of rustc and other core Rust development tools that offers stability for professional and high-integrity Rust projects. Critical fixes to GNAT Pro for Rust are upstreamed to the Rust community, and critical fixes made by the community to upstream Rust tools are backported as needed to the GNAT Pro for Rust code base. Additionally, the Assurance edition of GNAT Pro for Rust includes the "sustained branch" service (see *Sustained Branches* (page 2689)) that strikes the balance between tool stability and project flexibility.

143.7 Integrated Development Environments (IDEs)

143.7.1 GNAT Studio

GNAT Studio is a powerful and simple-to-use IDE that streamlines software development from the initial coding stage through testing, debugging, system integration, and maintenance. It is designed to allow programmers to get the most out of GNAT Pro technology.

Tools

GNAT Studio's extensive navigation and analysis tools can generate a variety of useful information including call graphs, source dependencies, project organization, and complexity metrics, giving a thorough understanding of a program at multiple levels. It allows interfacing with third-party version control systems, easing both development and maintenance.

Robust, Flexible and Extensible

Especially suited for large, complex systems, GNAT Studio can import existing projects from other Ada implementations while adhering to their file naming conventions and retaining the existing directory organization. Through the multi-language capabilities of GNAT Studio, components written in C and C++ can also be handled. The IDE is highly extensible;

additional tools can be plugged in through a simple scripting approach. It is also tailorable, allowing various aspects of the program's appearance to be customized in the editor.

Easy to learn, easy to use

GNAT Studio is intuitive to new users thanks to its menu-driven interface with extensive online help (including documentation on all the menu selections) and *tool tips*. The Project Wizard makes it simple to get started, supplying default values for almost all of the project properties. For experienced users, it offers the necessary level of control for advanced purposes; e.g., the ability to run command scripts. Anything that can be done on the command line is achievable through the menu interface.

Remote Programming

Integrated into GNAT Studio, Remote Programming provides a secure and efficient way for programmers to access any number of remote servers on a wide variety of platforms while taking advantage of the power and familiarity of their local PC workstations.

143.7.2 VS Code Extensions for Ada and SPARK

AdaCore's extensions to Visual Studio Code (VS Code) enable Ada and SPARK development with a lightweight editor, as an alternative to the full GNAT Studio IDE. Functionality includes:

- Syntax highlighting for Ada and SPARK files
- Code navigation
- Error diagnostics (errors reported in the Problems pane)
- Build integration (execution of GNAT-based toolchains from within VS Code)
- Display of SPARK proof results (green/red annotations from GNATprove)
- Basic IntelliSense (completion and hover information for known symbols)

143.7.3 Eclipse Support – GNATbench

GNATbench is an Ada development plug-in for Eclipse and Wind River's Workbench environment. The Workbench integration supports Ada development on a variety of VxWorks real-time operating systems. The Eclipse version is primarily for native applications, with some support for cross development. In both cases the Ada tools are tightly integrated.

143.7.4 GNATdashboard

GNATdashboard serves as a one-stop control panel for monitoring and improving the quality of Ada software. It integrates and aggregates the results of AdaCore's various static and dynamic analysis tools (GNATmetric, GNATcheck, GNATcoverage, SPARK Pro, among others) within a common interface, helping quality assurance managers and project leaders understand or reduce their software's technical debt, and eliminating the need for manual input.

GNATdashboard fits naturally into a continuous integration environment, providing users with metrics on code complexity, code coverage, conformance to coding standards, and more.

CHAPTER

FOUR

ADACORE CONTRIBUTIONS TO THE SOFTWARE QUALITY ASSURANCE PLAN

This chapter identifies AdaCore's tools and technologies that support the techniques and measures defined in the EN 50128 Annex A tables and that can be cited accordingly in the Software Quality Assurance Plan. The information is presented in the form of annotations on the relevant tables in Annex A. These annotations indicate whether a technique or measure is covered by an AdaCore tool or technology and, if so, a comment on how the tool or technology contributes is provided.

Summary of abbreviations:

- **M** → Mandatory
- **HR** → Highly Recommended
- **R** → Recommended
- **---** → Optional (neither Recommended nor Not Recommended)
- **NR** → Not Recommended

144.1 Table A.3 – Software Architecture (7.3)

The Ada language and AdaCore technology do not provide support for software architecture *per se*, but rather are more targeted towards software component design. However, the presence of some capabilities at the lower level may enable certain design decisions at a higher level. This table offers some guidance on how that can be done.

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Defensive Programming	D.14	HR	HR	Yes	Defensive programming is more a component or a programming activity than an architecture activity per se, but as it is recorded in this table, it's worth mentioning that the Ada language provides several features addressing various objectives of defensive programming techniques (e.g., exception handling). In addition, CodeSonar for Ada and the SPARK tools help identify pieces of code that should be protected by defensive code.
Fault Detection & Diagnosis	D.26	R	R	No	
Error Correcting Codes	D.19	—	—	No	
Error Detecting Codes	D.19	R	HR	No	
Failure Assertion Programming	D.24	R	HR	Yes	The Ada language allows formalizing assertions and contracts in various places in the code.
Safety Bag Techniques	D.47	R	R	No	
Diverse Programming	D.16	R	HR	Yes	Using Ada along with another language and a different code generation technology can be used to contribute to the diverse programming argument.
Recovery Block	D.44	R	R	No	
Backward Recovery	D.5	NR	NR	No	
Forward Recovery	D.30	NR	NR	No	
Retry Fault Recovery Mechanisms	D.46	R	R	No	
Memorising Executed Cases	D.36	R	HR	No	
Artificial Intelligence – Fault Correction	D.1	NR	NR	No	
Dynamic Reconfiguration of software	D.17	NR	NR	No	
Software Error Effect Analysis	D.25	R	HR	No	

continues on next page

Table 9 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Graceful Degradation	D.31	R	HR	No	
Information Hiding / Encapsulation	D.33	HR	HR	Yes	The Ada language provides the necessary features to separate the interface of a module from its implementation and enforce this separation.
Fully Defined Interface	D.38	HR	M	Yes	The Ada language provides the necessary features to separate the interface of a module from its implementation and enforce this separation.
Formal Methods	D.28	R	HR	Yes	SPARK can be used to formally define architectural properties, such as data flow, directly in the code and provides the means to verify them.
Modeling	Table A.17	R	HR	Yes	Ada and SPARK allow defining certain modeling properties in the code and provide means to verify them.
Structured Methodology	D.52	HR	HR	Yes	Structured Methodology designs can be implemented with Ada.
Modeling supported by computer aided design and specification tools	Table A.17	R	HR	No	

144.2 Table A.4 – Software Design and Implementation (7.4)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Formal Methods	D.28	R	HR	Yes	Component requirements and interfaces can be written in the form of formal boolean properties, using the Ada or SPARK languages. These properties are verifiable.
Modeling	Table A.17	HR	HR	Yes	Ada and SPARK allow defining certain modeling properties in the code and provide means to verify them.
Structured methodology	D.52	HR	HR	Yes	Structured Methodology designs can be implemented with Ada.

continues on next page

Table 10 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Modular Approach	D.38	M	M	Yes	A module can be represented as an Ada package, with a cohesive and well-defined functionality, a clear external interface in the visible part of the package spec, a private part whose visibility is limited to to its child units, and a body containing the implementation (which is only visible to its subunits).
Components	Table A.20	HR	HR	Yes	A component can be defined as a set of Ada packages, which can clearly define the interface to access the internal data, and the interfaces can be fully and unambiguously defined. This set of packages is typically identified within a project file (GPR file) and can be put into a version control system.
Design and Coding Standards	Table A.12	HR	M	Yes	There are available references for the coding standard. Verification can be automated in different ways: the GNAT compiler can define base coding standard rules to be checked at compile-time, with GNATcheck implementing a wider range of rules.
Analyzable Programs	D.2	HR	HR	Yes	The Ada language provide native features to improve program analysis, such as type ranges, parameter modes, and encapsulation. Tools such as GNATmetric and GNATcheck can help monitor the complexity of the code and prevent the use of overly complex code. CodeSonar for Ada allows making an assessment of program analyzability during its development. For higher SILs, the use of SPARK ensures that the subset of the language used is suitable for most the rigorous analysis.
Strongly Typed Programming Language	D.49	HR	HR	Yes	Ada is a strongly typed language.
Structured Programming	D.53	HR	HR	Yes	Ada supports all the usual paradigms of structured programming. In addition, GNATcheck can control additional design properties, such as explicit control flows, where subprograms have single entry and single exit points, and structural complexity is reduced.

Table 10 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Programming Language	Table A.15	HR	HR	Yes	Ada can be used for most of the development, while facilitating interfacing to other languages such as C or assembly.
Language Subset	D.35	—	HR	Yes	Ada is designed to support subsetting, possibly under the control of specific runtimes, GNATcheck, or with SPARK. Another possibility is to follow the recommendations in[668].
Object-Oriented Programming	Table A.22, D.57	R	R	Yes	If needed, Ada supports all the usual paradigms of object-oriented programming, in addition to safety-related features such as the Liskov Substitution Principle.
Procedural Programming	D.60	HR	HR	Yes	Ada supports all the usual paradigms of procedural programming.
Metaprogramming	D.59	R	R	No	

144.3 Table A.5 – Verification and Testing (6.2 and 7.3)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Formal Proof	D.29	R	HR	Yes	When Ada pre- and post-conditions are used, together with the SPARK subset of the language, formal methods can formally verify compliance of the implementation with these contracts.
Static Analysis	Table A.19	HR	HR	Yes	See Table A.19
Dynamic Analysis and Testing	Table A.13	HR	HR	Yes	See Table A.13

Table 11 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Metrics	D.37	R	R	Yes	GNATmetric can compute and report metrics, such as code size, comment percentage, cyclomatic complexity, unit nesting, and loop nesting. These can then be compared with standards.
Traceability	D.58	HR	M	No	
Software Error Effect Analysis	D.25	R	HR	Yes	GNAT Studio supports code display and navigation. CodeSonar for Ada can identify likely error locations in the code. This supports potential software error detection and analysis throughout the code.
Test Coverage for code	Table A.21	HR	HR	Yes	See Table A.21
Functional / Black-Box Testing	Table A.14	HR	HR	Yes	See Table A.14
Performance Testing	Table A.18	HR	HR	No	
Interface Testing	D.34	HR	HR	Yes	Ada's strong typing, together with its contract-based programming support, provides increased assurance to demonstrate that the software interfaces are correct. This can help improve software-to-software integration testing.

144.4 Table A.6 – Integration (7.6)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Functional and Black-box testing	Table A.14	HR	HR	Yes	GNATtest can generate a framework for testing.
Performance Testing	Table A.18	R	HR	Yes	Stack consumption can be statically computed using the GNATstack tool.

144.5 Table A.7 – Overall Software Testing (6.2 and 7.7)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Performance Testing	Table A.18	HR	M	Yes	Stack consumption can be statically computed using the GNATstack tool.
Functional and Black-box Testing	Table A.14	HR	M	Yes	GNATtest can generate a testing framework for testing.
Modeling	Table A.17	R	R	No	

144.6 Table A.8 – Software Analysis Techniques (6.3)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Static Software Analysis	D.13, D.37, Table A.19	HR	HR	Yes	See Table A.19.
Dynamic Software Analysis	Tables A.13, A.14	R	HR	Yes	See Tables A.13 and A.14.
Cause Consequence Diagrams	D.6	R	R	No	
Event Tree Analysis	D.22	R	R	No	
Software Error Effect Analysis	D.25	R	HR	Yes	GNAT Studio supports code display and navigation. CodeSonar for Ada can identify likely error locations in the code. These tools support both detection of potential software errors and analysis throughout the code.

144.7 Table A.9 – Software Quality Assurance (6.5)

Although AdaCore doesn't directly provide services for ISO 9001 or configuration management, it follows standards to enable tool qualification and/or certification. The following table only lists items that can be useful to third parties.

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Accredited to EN ISO 9001	7.1	HR	HR	No	
Compliant with EN ISO 9001	7.1	M	M	No	
Compliant with ISO/IEC 90003	7.1	R	R	No	
Company Quality System	7.1	M	M	No	
Software Configuration Management	D.48	M	M	No	
Checklists	D.7	HR	M	No	
Traceability	D.58	HR	M	No	
Data Recording and Analysis	D.12	HR	M	Yes	The data produced by tools can be written to files and placed under configuration management.

144.8 Table A.10 – Software Maintenance (9.2)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Impact Analysis	D.32	HR	M	Yes	CodeSonar for Ada contributes to identifying the impact of a code change between two baselines.
Data Recording and Analysis	D.12	HR	M	Yes	AdaCore tools can be invoked from the command line. They produce result files including the date and version of the tool used.

144.9 Table A.11 – Data Preparation Techniques (8.4)

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Tabular Specification Methods	D.68	R	R	Yes	Tables of data can be expressed using the Ada language, together with type-wide contracts (predicates or invariants).
Application specific language	D.69	R	R	No	
Simulation	D.42	HR	HR	No	
Functional testing	D.42	M	M	No	
Checklists	D.7	HR	M	No	
Fagan inspection	D.23	HR	HR	No	
Formal design reviews	D.56	HR	HR	Yes	GNAT Studio can display code and navigate through the code as a support for walkthrough activities.
Formal proof of correctness	D.29	—	HR	Yes	When contracts are expressed within the SPARK subset, their correctness can be formally verified.
Walkthrough	D.56	R	HR	Yes	GNAT Studio can display code and navigate through the code as a support for walkthrough activities.

144.10 Table A.12 – Coding Standards

There are available references for coding standards. Their verification can be automated through different ways: the GNAT compiler can define base coding standard rules to be checked at compile time, and GNATcheck implements a wider range of rules and is tailorable to support project-specific coding standards.

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Coding Standard	D.15	HR	M	Yes	GNATcheck allows implementing and verifying a coding standard.
Coding Style Guide	D.15	HR	HR	Yes	GNATcheck allows implementing and verifying a coding style guide.

continues on next page

Table 18 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
No Dynamic Objects	D.15	R	HR	Yes	GNATcheck can forbid the use of dynamic objects.
No Dynamic Variables	D.15	R	HR	Yes	GNATcheck can forbid the use of dynamic variables.
Limited Use of Pointers	D.15	R	R	Yes	GNATcheck can forbid the use of pointers or force justification of their usage.
Limited Use of Recursion	D.15	R	HR	Yes	GNATcheck can forbid the use of recursion or force justification of their usage.
No Unconditional Jumps	D.15	HR	HR	Yes	GNATcheck can forbid the use of unconditional jumps.
Limited size and complexity of Functions, Subroutines and Methods	D.38	HR	HR	Yes	GNATmetric can compute complexity measures, and GNATcheck can report excessive complexity.
Entry/Exit Point strategy for Functions, Subroutines and Methods	D.38	HR	HR	Yes	GNATcheck can verify rules related to exit points.
Limited number of subroutine parameters	D.38	R	R	Yes	GNATcheck can limit the number of parameters for subroutines and report when that number is exceeded.
Limited use of Global Variables	D.38	HR	M	Yes	GNATcheck can flag global variable usage and enforce their justification. SPARK forbids function side effects and enforces documentation and verification of uses of global variables. GNAT Studio allows analyzing usage of global variables.

144.11 Table A.13 – Dynamic Analysis and Testing

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Test Case Execution from Boundary Value Analysis	D.4	HR	HR	Yes	GNATtest can generate and execute a testing framework for tests written by developers from requirements.
Test Case Execution from Error Guessing	D.20	R	HR	Yes	GNAT fuzz can automate the generation of large numbers of test cases at a high frequency.
Test Case Execution from Error Seeding	D.21	R	HR	No	
Performance Modeling	D.39	R	HR	No	
Equivalence Classes and Input Partition Testing	D.18	R	HR	Yes	Ada and SPARK provide specific features for partitioning function input and verifying that this partitioning is well formed (i.e., no overlap and no gaps).
Structure-Base Testing	D.50	R	HR	Yes	See Table A.21

144.12 Table A.14 – Functional/Black Box Test

GNATtest can generate and execute a testing framework, with the actual tests being written by developers from requirements.

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Test Case Execution from Cause Consequence Diagrams	D6	—	R	No	
Prototyping/ Animation	D.43	—	R	No	
Boundary Value Analysis	D.4	R	HR	Yes	GNATtest can be used to implement tests coming from boundary value analysis.

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Equivalence Classes and Input Partitioning Testing	D.18	R	HR	Yes	Ada and SPARK provide specific features for partitioning function input and verifying that this partitioning is well formed (i.e., no overlap and no gaps).
Process Simulation	D.42 R	R	No		

144.13 Table A.15 – Textual Programming Language

Technique/Measure	SIL 2	SIL 3/4	Covered	Comment
Ada	HR	HR	Yes	GNAT Pro tools support all versions of the Ada language.
MODULA-2	HR	HR	No	
PASCAL	HR	HR	No	
C or C++	R	R	Yes	GNAT Pro for C and GNAT Pro for C++ support these languages
PL/M	R	NR	No	
BASIC	NR	NR	No	
Assembler	R	R	No	
C#	R	R	No	
Java	R	R	No	
Statement List	R	R	No	

144.14 Table A.17 – Modeling

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Data Modeling	D.65	R	HR	Yes	Ada allows modeling data constraints, in the form of type predicates.
Data Flow Diagram	D.11	R	HR	Yes	SPARK allows defining data flow dependencies at subprogram specification.
Control Flow Diagram	D.66	R	HR	No	
Finite State Machine or State Transition Programs	D.27	HR	HR	No	
Time Petri Nets	D.55	R	HR	No	
Decision/Truth Tables	D.13	R	HR	No	
Formal Methods	D.28	R	HR	Yes	SPARK allows defining formal properties on the code that can be verified by the SPARK toolset.
Performance Modeling	D.39	R	HR	No	
Prototyping/Animation	D.43	R	R	No	
Structure Diagrams	D.51	R	HR	No	
Sequence Diagrams	D.67	R	HR	No	

144.15 Table A.18 – Performance Testing

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Avalanche/Stress Testing	D.3	R	HR	No	Ada allows modeling data constraints, in the form of type predicates.
Response Timing and Memory Constraints	D.45	HR	HR	Yes	GNATstack can statically analyze stack usage.
Performance Requirements	D.40	HR	HR	No

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment

144.16 Table A.19 – Static Analysis

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Boundary Value Analysis	D.4	R	HR	Yes	CodeSonar for Ada can compute boundary values for variables and parameters from the source code. CodeSonar for Ada and SPARK can verify various properties by analyzing potential values and boundary values of variables. This includes detecting errors such as dereferencing a pointer that could be null, generating a value outside the bounds of an Ada type or subtype, violating a memory safety constraint (*buffer overrun*), generating a numeric overflow or wraparound, and dividing by zero. CodeSonar for Ada and SPARK also help to confirm expected boundary values of variables and parameters coming from the design.
Checklists	D.7	R	R	No	
Control Flow Analysis	D.8	HR	HR	Yes	CodeSonar for Ada and SPARK can detect suspicious and potentially incorrect control flows, such as unreachable code, redundant conditionals, loops that either run forever or fail to terminate normally, and subprograms that never return. GNATstack can analyze control flow and compute the maximum amount of stack memory for each task. More generally, GNAT Studio provides visualization for call graphs and call trees.

continues on next page

Table 24 – continued from previous page

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Data Flow Analysis	D.10	HR	HR	Yes	CodeSonar for Ada and SPARK can detect suspicious and potentially incorrect data flow, such as variables being read before they are written (uninitialized variables), and values that are written to variables without being read (redundant assignments).
Error Guessing	D.20	R	R	Yes	Although realized through dynamic rather than static analysis, GNAT fuzz can automatically generate test cases to support Error Guessing.
Walkthroughs/Design Reviews	D.56	HR	HR	Yes	GNAT Studio can display and navigate the code, supporting walkthrough activities.

144.17 Table A.20 – Components

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Information Hiding	D.33	—	—	Yes	See Information Encapsulation below.
Information Encapsulation	D.33	HR	HR	Yes	Ada provides the necessary features to separate the interface of a module from its implementation, and enforce this separation.
Parameter Number Limit	D.38	R	R	Yes	GNATcheck can limit the number of parameters for subroutines, and report violations.
Fully Defined Interface	D.38	HR	M	Yes	Ada offers many features to support interface definition, including behavior specification through pre- and post-conditions.

144.18 Table A.21 – Test Coverage for Code

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Statement	D.50	HR	HR	Yes	GNATcoverage provides statement-level coverage capabilities.
Branch	D.50	R	HR	Yes	GNATcoverage provides branch-level coverage capabilities.
Compound Condition	D.50	R	HR	Yes	GNATcoverage provides MC/DC (Modified Condition/Decision Coverage) capabilities, which can be used as an efficient alternative to Compound Condition coverage.
Data Flow	D.50	R	HR	No	
Path	D.50	R	NR	No	

144.19 Table A.22 – Object Oriented Software Architecture

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Traceability of the concept of the application domain to the classes of the architecture	—	R	HR	No	
Use of suitable frames, commonly used combinations of classes and design patterns	—	R	HR	Yes	The conventional OO design patterns can be implemented in Ada.
Object Oriented Detailed Design	Table A.23	R	HR	Yes	See Table A.23

144.20 Table A.23 – Object Oriented Detailed Design

Technique/Measure	Ref	SIL 2	SIL 3/4	Covered	Comment
Class should have only one objective	—	R	HR	Yes	It's possible in Ada to write classes with a unique objective.
Inheritance used only if the derived class is a refinement of its basic class	—	HR	HR	Yes	Ada and SPARK can enforce respecting the Liskov Substitution Principle, ensuring inheritance consistency.
Depth of inheritance limited by coding standards	—	R	HR	Yes	GNATcheck can limit inheritance depth.
Overriding of operations (methods) under strict control	—	R	HR	Yes	Ada can enforce explicit syntax for overriding methods.
Multiple inheritance used only for interface classes	—	HR	HR	Yes	Ada only allows multiple inheritance from interfaces.
Inheritance from unknown classes	—	—	NR	Yes	Ada only allows inheritance from known classes.

CHAPTER

FIVE

TECHNOLOGY USAGE GUIDE

This chapter explains how AdaCore's tools and technologies support a variety of techniques from Annex D.

145.1 Analyzable Programs (D.2)

The Ada language has been designed to increase program specification expressiveness and verification. Explicit constraints at the code level can be used as the basis of both manual analysis (inspection), such as code reviews, and automatic analysis, ranging from the compiler's semantic consistency checks to the SPARK tools' formal proof of program properties.

Examples of Ada language features supporting analysis include:

- type and subtype ranges and predicates
- parameter modes and subprogram contracts
- packages and private types (encapsulation)
- the Ravenscar concurrency profile
- minimal set of implicit or undefined behaviors

Tools such as GNATmetric and GNATcheck allow monitoring the complexity and quality of the code and identifying potentially problematic constructs. This is accomplished through techniques such as basic code size metrics, cyclomatic complexity computation, and coupling analysis.

CodeSonar for Ada identifies potential run-time errors in the code. The number of false positive results depends on the code complexity. A high number of false positives is often a symptom of overly-complicated code. Using CodeSonar for Ada during development allows finding locations in the code that are overly complex and provides information on what needs to be improved.

The SPARK language is much more ambitious in analyzing programs, at the extreme supporting full correctness proofs against formally specified requirements. It structurally forbids features such as exceptions, which complicate or prevent formal analysis. Code that is hard to analyze is often hard to understand and maintain, and conversely. Using SPARK as part of the development phase thus results in code that is not only maximally analyzable but also clear and readable.

During code review phases, GNAT Studio offers a variety of features that can be used for program analysis, in particular call graphs, reference searches, and other code organization viewers.

145.2 Boundary Value Analysis (D.4)

The objective of this technique is to verify and test the behavior of a subprogram at the limits and boundary values of its parameters. AdaCore's technologies can provide complementary assurance on the quality of this analysis and potentially decrease the number of tests that need to be performed.

Ada's strong typing allows refining types and variables boundaries. For example:

```
type Temperature is new Float range -273.15 .. 1_000;
V : Temperature;
```

Additionally, it's possible to define the specific behavior of values at various locations in the code. For example, it's possible to define relationships between the input and output of a subprogram, in the form of a partitioning of the input domain:

```
function Compute (J : Integer) return Integer
   with Contract_Cases => (J = Integer'First => Compute'Result = -1,
                           J = Integer'Last  => Compute'Result = 1,
                           others            => J - 1);
```

The above shows an input partition of one parameter (but it can also be a combination of several parameters). The behavior on the boundaries of J is specified and can then either be tested (for example, with enabled assertions) or formally proven with SPARK. Further discussion of input partitioning can be found in the context of *Equivalence Classes and Input Partition Testing (D.18)* (page 2721).

Another possibility is to use CodeSonar for Ada to identify possible values for variables, and propagate those values from call to call, constructing lists and/or ranges of potential values for each variable at each point of the program. These are used as the input to run-time error analysis. When used in full-soundness mode, CodeSonar for Ada provides guarantees that the locations it reports on the code are the only ones that may have run-time errors, thus allowing a reduction of the scope of testing and review to only these places.

However, it's important to stress that CodeSonar for Ada is only performing this boundary value analysis with respect to potential exceptions and robustness. No information is provided regarding the correctness of the values produced by subprograms.

CodeSonar for Ada also has the capacity to display the possible values of variables and parameters. This can be used as a mechanism to increase confidence that testing has taken into account all possible boundaries for values.

SPARK has the ability to perform similar absence of run-time errors (AORTE) analysis, thus reaching the same objectives. In addition to the above, when requirements can be described in the form of boolean contracts, SPARK can demonstrate correctness of the relation between input and output on the entire range of values.

145.3 Control Flow Analysis (D.8)

Control flow analysis requires identifying poor and incorrect data structures, including unreachable code and useless tests in the code (such as conditions that are always true).

GNAT Studio can display call graphs between subprograms, allowing visualization and analysis of control flow in the application.

CodeSonar for Ada contributes to control flow analysis by identifying unreachable code, as well as conditions being always true or always false. This analysis is partial and needs to be completed with other techniques such as code review or code coverage analysis, which together will allow reaching higher levels of confidence.

GNATmetric can compute coupling metrics between units, helping to identify loosely or tightly coupled units.

GNATstack computes worst-case stack consumption based on the application's call graph. This can help identify poorly structured code which consumes too much memory on some sequences of calls.

145.4 Data Flow Analysis (D.10)

The GNAT Pro toolchain can be configured to detect uninitialized variables at run-time through the use of the pragma `Initialize_Scalars`. With this pragma, all scalars are automatically initialized to either an out-of-range value (if there is one) or to an *unusual* value (either the largest or smallest). This significantly improves detection at test time.

CodeSonar for Ada can detect suspicious and potentially incorrect data flows, such as variables that are read before they are written (uninitialized variables), variables written more than once without being read (redundant assignments), and variables that are written but never read. This analysis is partial and needs to be completed with other techniques such as formal proof, code review or code coverage analysis, which together allow reaching higher levels of confidence.

SPARK performs this analysis and much more, allowing the specification and verification of data flow. This is used in the following activities:

- verification that all inputs and outputs have been specified, including possible side effects
- verification that all dependencies between inputs and outputs are specified
- verification that the implemented dataflow corresponds to the one specified

Here's an example:

```
procedure Compute (A, B, C : Integer; R1, R2 : out Integer)
   with Depends => (R1 => (A, B),
                    R2 => (B, C));

procedure Compute (A, B, C : Integer; R1, R2 : out Integer) is
begin
   R1 := A + B;
   R2 := A + B - C;
end Compute;
```

R1 is required to be computed from A and B, and R2 from B and C. However, in the procedure body, R2 also depends on A. SPARK's formal proof detects this error.

The error is likewise detected in the presence of branches:

```
procedure Compute (A, B, C : Integer; R1, R2 : out Integer) is
begin
   R1 := A + B;
   if A = 0 then
      R2 := B + C;
   else
      R2 := B - C;
   end if;
end Compute;
```

Here R2 depends on the result of the expression `A = 0`, so its value is actually computed from A, B and C, and not just B and C. As in the previous case, SPARK's formal analysis detects the error.

A similar result occurs when the dependence is indirect, through a subprogram call. Here's an example based on a logging procedure that has a global state, Screen, which is written to by the procedure:

```
procedure Log (V : String)
   with Global  => (Output => Screen),
        Depends => (Screen => V)

procedure Compute (A, B, C : Integer; R1, R2 : out Integer)
  with Depends => (R1 => (A, B),
                   R2 => (B, C));

procedure Compute (A, B, C : Integer; R1, R2 : out Integer) is
begin
   R1 := A + B;
   R2 := B + C;

   if A = 0 then
      Log ("A is 0");
   end if;
end Compute;
```

The data flow does not correspond to the specification: Compute should specify that it modifies Screen. So the incorrect code is detected. The error is detected whether or not a branch is present, serving as a useful complement to structural code coverage in many cases.

145.5 Defensive Programming (D.14)

As stated in sub-clause D.14, the goal of defensive programming is to "detect anomalous control flow, data flow, or data values ... and react to them in a predetermined and acceptable manner".

Ada's strong typing will avoid the need for many situations where constraints would be expressed in the form of defensive code. However, in some situations strong typing is not enough. This can be the case, for example, when accessing an element of an array. In this case, Ada allows expressing constraints in the specification, through preconditions, postconditions or predicates.

Beyond this, Ada provides specific support for a subset of what's specified in the D.14 annex. CodeSonar for Ada and SPARK will allow the development of defensive programming in places where it makes the most sense.

Specific defensive code rules can also be defined in the coding standard and their verification can then be automated through code analysis using, for example, GNATcheck.

145.5.1 Data should be range checked

Ada offers types and subtypes that are naturally associated with ranges, e.g.:

```
subtype Percent is Integer range 0 .. 100;
-- Percent is the same type as Integer but with a run-time constraint on its range

X, Y : Integer;
V    : Percent;
...
V := X + Y; -- Raises exception Constraint_Error if X + Y is not in 0 .. 100
...
```

It's then the task of the developer to react to potential exceptions. Alternatively, it's possible to write explicit verification in the code to ensure that the expression is within its boundary:

```
V_Int : Integer;
V_Pct : Percent;
...
V_Int := X+Y;
if V_Int in Percent then
   V_Pct := V_Int;
else
  ... -- Respond to out-of-range result
end if;
```

Another way to proactively ensure the absence of range check failure is to use tools such as CodeSonar for Ada or SPARK, which statically identify the only possible locations in the code where such failures can happen.

Note that run-time checks can be deactivated if needed for performance reasons, for example once thorough testing or formal proof has been performed.

145.5.2 Data should be dimension-checked

The GNAT Pro compiler provides a language extension for dimensional consistency analysis, which ensures that variables are properly typed according to their dimension. The system is implemented based on the seven base dimensions (meter, kilogram, second, ampere, kelvin, mole, candela), and will check that operations between these types are consistent. For example, a type Speed can be defined to represent distance per time. Consistency between these types is checked at compile time so that dimension errors will be reported as errors. For example:

```
D       : Distance := 10;
T       : Time     := 1;
S       : Speed    := D / T; -- OK
My_Time : Time     := 100;
...
Distance_Traveled := S / My_Time;
-- Error, resulting dimension is Distance / Time**2
-- The expression should be S * My_Time
```

145.5.3 Read-only and read-write parameters should be separated and their access checked

In Ada, the parameter mode is specified in parameter specifications and is checked by the compiler. For example, a read-only parameter is passed as mode **in** and may not be modified. A read-write parameter is passed either as mode **in out** or as mode **out** and is modifiable. (The **out** mode is appropriate if the parameter is written before being read). The compiler will produce an error for an attempted modification of **in** parameters and detect when an **in out** or **out** parameter is not modified and so could have been passed as **in**. For example:

```
procedure P (V : in Integer) is
begin
   V := 5; -- ERROR, V is mode "in"
end P;
```

145.6 Functions should treat all parameters as read-only

The original version of Ada required that functions could only have **in** parameters. This restriction was relaxed in a later version of the standard, but the original behavior can be

reverted through a GNATcheck rule. The SPARK Ada subset forbids functions with writable (i.e., **out** or **in out** parameters).

145.6.1 Literals and constants should not be write-accessible

Ada provides many kinds of literals (e.g. numeric, character, enumeration, string) and allows declaring constants of any type but ensures that their values can not be updated.

```
type Color is (Red, Blue, Green);
Answer    : constant Integer := 42;
One_Third : constant         := 1.0 / 3.0;
Greeting  : String           := "Hello";
```

The literals and constants are read-only as per language definition. For example, trying to pass Red or Answer to a subprogram as an **out** or **in out** parameter would be illegal. Note that Greeting is a variable and can be assigned to, but the literal "Hello" is immutable.

145.6.2 Using CodeSonar for Ada and SPARK to drive defensive programming

CodeSonar for Ada and SPARK identify locations where there are potential run-time errors — in other words, places where code is either wrong or where defensive programming should be deployed. This helps guide the writing of defensive code. For example:

```
procedure P (S : String; V : Integer) is
   C : Character;
begin
   ...
   C := S (V);
   ...
end P;
```

In the above code, there's a use of V as an index into the String S. CodeSonar for Ada and SPARK will detect the potential for a run-time error. Protection of the code to prevent the error can take several forms:

Explicit test

The application code checks that V is in range before using its value as an index into the String. If the check fails, the appropriate recovery action can be taken (here the procedure simply returns).

```
procedure P (S : String; V : Integer) is
   C : Character;
begin
   ...
   if V not in S'Range then
      return;
   end if;
   C := S (V)
   ...
end P;
```

Precondition

Here the error is detected at call time. If assertion checking is enabled and the check fails, the Assertion_Check exception is raised.

```
procedure P (S : String; V : Integer)
   with Pre => V in S'Range
is
   C : Character;
begin
   ...
   C := S (V);
   ...
end P;
```

The main difference between CodeSonar for Ada and SPARK is that CodeSonar for Ada may miss some potential run-time errors (except when run only on small pieces of code if configured in "sound" mode), while SPARK requires the use of the appropriate Ada subset but is a sound technology (i.e., it will detect all potential run-time errors).

In general, the recommended Ada style is to use contracts instead of defensive code.

145.7 Coding Standards and Style Guide (D.15)

A coding standard can be defined using a combination of predefined rules (using GNAT options and GNATcheck rules) and appropriate arguments to pragma `Restrictions`.

145.8 Equivalence Classes and Input Partition Testing (D.18)

This technique involves partitioning the various potential inputs to subprograms and creating a testing and verification strategy based on this partitioning.

Ada extensions included in GNAT Pro for Ada can support partitioning at the source code level. The partition is a list of conditions for inputs together with their associated expected output, verifying the following criteria:

- The full set of all potential values is covered
- There is no overlap between partitions

These criteria can be verified either dynamically, by verifying at test time that all inputs exercised fall into one and only one partition, or formally by SPARK, proving that the partitions are indeed complete and disjoint.

Here's a simple example of such partitioning with two input variables:

```
function ArcTan (X, Y : Float) return Float with
   Contract_Cases =>
      (X >= 0 and Y >= 0 => ArcTan'Result >= 0         and ArcTan'Result <= PI/2,
       X <  0 and Y >= 0 => ArcTan'Result >= PI/2      and ArcTan'Result <= PI,
       X <  0 and Y < 0  => ArcTan'Result >= PI        and ArcTan'Result <= 3 * PI/
↪2,
       X >= 0 and Y < 0  => ArcTan'Result >= 3 * PI/2 and ArcTan'Result <= 2 * PI);
```

The presence of these contracts enable further verification. At run time, they act as assertions and allow verification that the form of the output indeed corresponds to the expected input. If SPARK is used, it's possible to formally verify the correctness of the relation between the input and properties.

145.9 Error Guessing (D.20)

The GNATfuzz tool for fuzz testing (part of the GNAT Dynamic Analysis Suite) supports the Error Guessing technique and can provide evidence for a system's robustness. GNATfuzz exercises a program with a large number of automatically generated test values, often random or malformed, and checks for crashes, hangs, and other anomalous behavior.

145.10 Failure Assertion Programming (D.24)

Ada offers a large variety of assertions (contracts) that can be defined in the code, either through pragmas or aspects.

- Pragma `Assert`

  This pragma allows verification within a sequence of statements:

```
A := B + C;
pragma Assert (A /= 0);
D := X / A;
```

- Pre- and postcondition contracts

  Pre- and postconditions can be defined as subprogram aspects:

```
procedure Double (X : in out Integer)
   with Pre  => X < 100,
        Post => X = X'Old * 2;
```

- Predicates and invariants

  Predicate and invariant contracts can be defined on types:

```
type Even is new Integer
with Dynamic_Predicate => Even mod 2 = 0;
```

These contracts can be checked dynamically, for example, during testing. The developer has fine control over which contracts can be removed (e.g. for improved performance) and which should remain in the deployed software.

The contracts can be used by the static analysis and formal proof tools. CodeSonar for Ada uses contracts to refine its analysis and exploits them as assertions, even if it may not be able to demonstrate that they are correct. In this manner, contracts provide the tool with additional information on the code behavior. SPARK can go further and either prove their correctness, or else report its inability to do so. (In the latter case, the issue is either that the contract or the code is incorrect, or that the proof engine is not powerful enough to construct a proof.)

145.11 Formal Methods (D.28)

With SPARK, formal methods are used to define and check certain architectural properties, in particular for data coupling specification and verification. For example:

```
G : Integer;

procedure P (X, Y : Integer)
with Global => (Output => G),
     Depends => (G => (X, Y));
```

In the above example, the side effect of the subprogram is fully defined: P is modifying G. SPARK will check that this side effect, and no other, is present. G is specified as depending on the values of X and Y. Again, SPARK will analyze the code to check that the variable relationships specified are correct.

In this example, an actual variable is used to define data flow. It's also possible to create an *abstract* state, implemented by a set of variables. Generally speaking, although these notations and verifications are quite useful on the lower levels of the architecture, they may not be that pertinent at higher levels. SPARK is flexible with regard to where this should be checked or where it should not.

At the lower level of the design phases, some properties and requirements can be refined or specified in the form of boolean expressions. SPARK will allow expressing these properties, including the formalism of first-order logic (quantifiers). These properties can be expressed in the form of subprogram preconditions, postconditions, type invariants and type predicates. For example:

```
-- P must have an input greater or equal to 10, and then has to modify V.
procedure P (V : in out Integer)
with Pre  => V     >= 10,
     Post => V'Old /= V;

-- Variables of type Even must be even
type Even is new Integer
with Dynamic_Predicate => Even mod 2 = 0;

-- Arrays of this type are always sorted in ascending order
type Sorted_Array is array (Integer range <>) of Integer
with Dynamic_Predicate =>
   Sorted_Array'Size <= 1 or else
   (for all I in Sorted_Array'First .. Sorted_Array'Last - 1 =>
       Sorted_Array (I) <= Sorted_Array (I + 1));
```

These properties can be formally verified through the SPARK toolset, using state of the art theorem proving methodologies. Testing aimed at verifying the correctness of these properties can then be simplified, if not entirely removed.

145.12 Impact Analysis (D.32)

Identifying the effect of a change on an entire software component requires the combination of various techniques, including reviews, testing and static analysis. CodeSonar for Ada has specific features to identify the impact of a change from the perspective of potential run-time errors. It can establish a baseline with regard to potential failure analysis and filter only the potential defects that have been introduced or repaired following a change in the code.

GNAT Studio can provide call graphs and call trees, allowing the developer to see how a function is called in the software. This can be directly used in impact analysis.

145.13 Information Encapsulation (D.33)

Information encapsulation is good software engineering practice, enforcing access to data on a "need to know" basis and preventing hard-to-detect bugs from erroneous updates to global variables. Encapsulation has been intrinsic to the Ada design since the earliest version of the language and is embodied in the syntax and semantics of a variety of language features.

Ada's approach to encapsulation achieves similar methodological benefits to Object-Oriented Programming, but with a different syntax. In most OO languages, a class is both a

type (which can be instantiated to produce objects) and a module (which can be separately compiled). Ada separates these concepts, modeling a class by a type (typically a private type, as will be shown below) defined with a package (the main unit of modularization in Ada).

Separation of specification and body

The various program units in Ada — packages, tasks, subprograms, generic templates — have a structure that supports the separation of the unit's specification (its interface to other units) and its implementation (inaccessible externally). This physical separation not only supports encapsulation but also facilitates independent development of the two parts. For example, a package specification can be produced during the detailed design phase, with the body fleshed out later, perhaps by a different developer, during the implementation phase.

Package structure

A package comprises at least a specification and, if necessary, a body that implements the subprograms and other entities whose specifications are in the package specification. The package specification in general consists of a visible part and a private part. In a typical scenario, the visible part declares a type as **private**, along with subprogram specifications for the operations that are relevant to that type. The type and operations form the interface for that type. The private part of the package specification then provides the full declaration of the type, and the package body supplies the bodies for the subprograms defined for the type.

External to the package, the type name and the operations defined for the type are accessible, but the representational details for the full type declaration are hidden. This allows the designer of the package to modify the representation of the type during development or maintenance, without requiring source code changes to client code. This principle is sometimes referred to as *data abstraction*. Here is an example:

```
package Counters is
   type Counter is private;
   --  We don't want to give access to the representation of the counter here

   procedure Increment (C : in out Counter);
   procedure Print (C : in out Counter);

private

   type Counter is new Integer;
    -- Here, Counter is an Integer, but it could change to something
    -- else if needed without disturbing the interface.
end Counters;

with Ada.Text_IO;
package body Counters is
   procedure Increment (C : in out Counter) is
   begin
      C := C + 1;
   end Increment;

   procedure Print (C : in out Counter) is
   begin
      Ada.Text_IO.Put_Line (C'Img);
   end Print;
end Counters;
```

As a variation on this example, Ada supports encapsulation through *getter* and *setter* subprograms. Rather than directly manipulating a global variable declared in a package speci-

fication, the program can be structured to enforce accesses through a procedural interface:

```
package Data is
   function Value return Integer;       -- "Getter" function
   procedure Set (New_Value : Integer); -- "Setter" procedure
end Data;

package body Data is
   Global : Integer := 0;

   function Value return Integer is
   begin
      return Global;
   end Value;

   procedure Set (New_Value : Integer) is
   begin
      Value := New_Value;
   end Set;
end Data;
```

Concurrency

Both of Ada's tasking constructs — the task and the protected object — enforce encapsulation.

- A task object or task type specification defines its interface (its entries, which are used for synchronization and communication), and its body defines the implementation.
- A protected object or protected type specification defines its interface (entries and procedures, which are executed with mutual exclusion), and its body defines the implementation. The private part of a protected object/type specification encapsulates the data that is being protected: it can only be accessed externally through the entries and procedures that it defines.

Representation clauses

As another form of encapsulation, Ada's representation clause facility separates an entity's logical properties — its interface to client code — and its representation. For example:

```
type Alert is (Low, Medium, High);

type Packet is record
  Flag :   Boolean;
  Danger : Alert;
  Data :   Interfaces.Unsigned_8;
end record;

Byte : constant := 8;

for Alert use (Low => 0, Medium => 5, High => 10);
for Alert'Size use 4;

for Packet use record
   Flag   at 0*Byte range 3 .. 3;  -- Bits 1..2 are unused
   Danger at 0*Byre range 4 .. 7;
   Data   at 1*Byte range 0 .. 7;
end Packet;
for Packet'Size use 2*Byte;
```

145.14 Interface Testing (D.34)

Ada allows extending the expressiveness of an interface specification at the code level, allowing constraints such as:

- parameter passing modes
- pre- and postconditions
- input partitioning
- typing

These are each described in other sections of this document. These specifications can help the development of tests around the interface, formalize constraints on how the interface is supposed to be used, and activate additional dynamic checking or formal proofs (through SPARK), all ensuring that users are indeed respecting the expectations of the interface designer.

In addition, GNATtest can generate a testing framework to implement interface testing, and GNATfuzz can help by probing the robustness of the system when interface requirements are violated.

145.15 Language Subset (D.35)

The Ada language has been designed to facilitate subsetting, since its targeted domain — long-lived safety-critical embedded systems — often involves small-footprint applications that need to be certified under demanding software standards. The full language would be inappropriate with such constraints, and Ada provides a general feature — pragma Restrictions — to allow subsetting on a user-selectable basis. For example, with `pragma Restrictions (No_Abort_Statements)` the program will be rejected by the compiler if it contains an `abort` statement.

Going one step further, the language standard has bundled a set of restrictions into a so-called profile — the Ravenscar Profile — that supports common concurrency idioms (e.g. periodic and sporadic tasks) and can make a tasking program deterministic and statically analyzable.

SPARK is a natural Ada language subset, constraining the language so that programs can be subject to formal analysis (e.g., safe pointers, no aliasing, and no exceptions).

Other language subsets can be supplied by the implementation, such as the features implemented by the GNAT Pro Certifiable Profiles. And with GNATcheck the user can in effect define a subset in an *à la carte* fashion, to specify prohibited constructs and verify that they are not present in the code.

145.16 Metrics (D.37)

The GNATmetric tool reports various metrics on the code, from simple structural metrics such as lines of code or number of entities to more complex computations such as cyclomatic complexity or coupling.

Custom metrics can be computed based on these first-level metrics. In particular, the GNATdashboard environment allows gathering all metrics into a database that can then be accessed through Python or SQL.

These metrics can be viewed through various interfaces.

145.17 Modular Approach (D.38)

145.17.1 Connections between modules shall be limited and defined, coherence shall be strong

Ada allows the developer to define group of packages that have different levels of coupling, through the notions of *child packages* and *private packages* as described below. In addition, the GNAT Pro technology provides the notion of a *project*, which defines a group of packages, possibly with a defined interface. These constructs can be used to define a tool-supported notion of *component* or *module* at the software level.

There are three main types of dependence between compilation units:

- Loose coupling through `with` clauses. If unit `Q` `with`s unit P, then `Q` can only access the entities in the visible part of P.
- Medium coupling through public child units. If P is a package, then child `P.Q` has visibility privileges that would not be available to a unit that only `with`s P. More specifically, `P.Q`, which is said to be a *public child*, can access the entities in the visible part of P. However, only the private part and body of `P.Q` can access the entities in the private part of P. And the entities declared in the body of P are only accessible in the package body itself.
- Tight coupling through private child units. As a generalization of public child units, if `P.Q` is declared as a *private* child, then the visible part of `P.Q` can also access the entities in the private part of P. This does not compromise encapsulation; the only units that can `with` a private child are units that otherwise would have access to the entities that the private child can see.

Ada's expressiveness makes it easier to develop large software systems, with precise control over the coupling between modules, and guaranteeing that data are only accessed by the intended units.

A typical example is the implementation of a complex system that needs to be spread across several packages. For example, suppose that packages `Communication` and `Interfaces`, contribute to the implementation of a signaling protocol. In Ada, this design can be implemented in three (or more) distinct files:

```
package Signaling is ...
private package Signaling.Communication is .
private package Signaling.Interfaces is ...
```

The two private packages are defined in separate files. They are private children of `Signaling`, which means they can only be used by the implementation of `Signaling`, and not by any module outside of the hierarchy.

In addition, tools can provide metrics on coupling between packages. GNATmetric has built-in support for retrieving these numbers.

At a coarser granularity, packages can be grouped together into a GNAT Project file (*GPR*), with a clear interface. An application architecture can be defined as a combination of project files.

145.17.2 Collections of subprograms shall be built providing several level of modules

Following the above example, it's possible to create public sub-modules as well, creating a hierarchy of services. Public child units are accessible to client code.

145.17.3 Subprograms shall have a single entry and single exit only

The GNATcheck tool has specific rules to verify this property on any Ada code.

145.17.4 Modules shall communicate with other modules via their interface

This is built-in to the Ada language. It's not possible to circumvent a package's interface. If a module is implemented using a coarser granularity, e.g. as a group of packages or at project level, then the project file description allows identifying those packages that are part of the interface and those packages that are not.

145.17.5 Module interfaces shall be fully documented

Although this is mostly the responsibility of the developer, Ada contracts can be used to formalize part of the documentation associated with a package interface, using a formal notation that can be checked for consistency by the compiler. This addresses the part of the documentation that can be expressed through boolean properties based on the software-visible entities.

145.17.6 Interfaces shall contain the minimum number of parameters necessary

The GNAT Pro compiler will warn about parameters not used by a subprogram implementation.

145.17.7 A suitable restriction of parameter number shall be specified, typically 5

GNATcheck allows specifying a maximum number of parameters per subprogram.

145.17.8 Unit Proof and Unit Test

GNATtest can be used to generate a unit testing framework for Ada applications.

SPARK performs a modular formal verification: it proves the postcondition of a subprogram according to its own precondition and the precondition and postconditions of its callees, whether or not these callees are themselves proven.

For a complete proof, all the subprograms of an application need to be formally proven. Where this is not possible, one subset can be proven and the other can be assumed to be true. These assumptions can then be verified using traditional testing methodology, allowing for a hybrid test / proof verification system.

145.18 Strongly Typed Programming Languages (D.49)

Ada is, from its inception, a strongly typed language, which supports both static and dynamic verification.

From a static verification point of view, each type is associated with a representation and a semantic interpretation. Two types with similar representations but different semantics will still be considered different by the compiler. For example:

```
type Kilometers is new Float;
type Miles is new Float:
```

These are distinct types. The compiler will not allow mixed operations, for example assigning a `Kilometers` value to a `Miles` variable, or adding a `Kilometers` value and a `Miles` value, unless explicit conversions are used. Mixing floating point and integer values is similar: the developer is responsible for deciding where and how conversion should be made.

From a dynamic verification point of view, types can be associated with constraints, such as value ranges or arbitrary boolean predicates. These type ranges and predicates will be verified at specific points in the application, allowing the early detection of inconsistencies.

145.19 Structure Based Testing (D.50)

AdaCore provides three tools to support structure based testing:

- GNATtest is a unit testing framework generator. It will run on Ada specifications, and generate a skeleton for each subprogram. The actual test can then be manually written into that skeleton.
- GNATemulator allows emulating code for a given target (e.g. PowerPC and Leon) on a host platform such as Windows or Linux. It's particularly well suited for running unit tests.
- GNATcoverage performs structural coverage analysis from an instrumented platform (GNATemulator or Valgrind on Linux or directly on a board through a Nexus probe). It supports statement coverage and decision coverage as well as MC/DC. Note that although EN 50128 requires compound condition coverage, Modified Condition/Decision Coverage (MC/DC) is usually accepted as a means of compliance.

145.20 Structured Programming (D.53)

The Ada language supports all the usual paradigms of structured programming. Complexity can be controlled with various tools, see *Analyzable Programs (D.2)* (page 2715) for more details.

145.21 Suitable Programming Languages (D.54)

Ada is noted as "Highly Recommended" in the list of programming languages. Some features may, however, not be suitable for the highest SIL. To enforce the detection and rejection of specific features, the developer can specify a language subset; see *Language Subset (D.35)* (page 2726).

One of the advantages of the Ada language is that it is precisely defined in an international document, ISO/IEC 8652. This document specifies the required effect as well as any implementation-defined behavior for the core language, the standard Ada libraries (known as the "predefined environment"), and the specialized needs annexes.

145.22 Object Oriented Programming (D.57)

Ada supports the usual constructs for object-oriented programming, but, for reasons of simplicity and reliability, with multiple inheritance limited to `interface` types. In addition, the Liskov Substitution Principle can be verified through class-wide contracts and SPARK formal verification, allowing the verification of class hierarchy consistency and the safety of dispatching operations.

Ada's OOP model is particularly well suited to safety-critical applications, as it allows instantiating objects on the stack. For example:

```
type Base_Class is tagged ...; -- Base_Class is the root of a class hierarchy
procedure P (X : Base_Class);
...
type Subclass is new Base_Class with ...;
overriding procedure P (X : Subclass);

B : Base_Class := ... -- on the stack
S : Subclass   := ... -- on the stack

X : Some_Type'Class := (if .. then B else S):
P (X);  -- Dispatches to appropriate version of P
```

In the above code, X is a polymorphic object that can be initialized with a value from any class in the hierarchy rooted at `Base_Class`; here it will be a value from either `Base_Class` or `Subclass`. Storage for X is reserved on the stack, and the invocation `P (X)` will dispatch to the appropriate version of P.

The booklet[669] provides additional information on how to use object-oriented features in a certified context.

145.23 Procedural Programming (D.60)

Ada implements all the usual features of procedural programming languages, with a general-purpose data type facility and a comprehensive set of control constructs.

CHAPTER

SIX

TECHNOLOGY ANNEX

This annex summarizes how AdaCore's tools and technologies support the various techniques and measures defined in Annex D of EN 50128. The qualification status for tools, and certifiability for run-time libraries, are also noted.

146.1 Ada Programming Language

See *Ada* (page 2683).

146.1.1 Qualification

Although there is no qualification of a language *per se*, the Ada language is standardized through an official process managed by an ISO committee, IEC/ISO 8652. AdaCore's Ada compilers and tools have reference and user documentation that precisely describes the expected behavior, including the effects of implementation-defined features.

146.1.2 Annex D References

- D.2 Analyzable Programs
- D.4 Boundary Value Analysis
- D.14 Defensive Programming
- D.18 Equivalence Classes and Input Partition Testing
- D.24 Failure Assertion Programming
- D.33 Information Hiding / Encapsulation
- D.34 Interface Testing
- D.35 Language Subset
- D.38 Modular Approach
- D.49 Strongly Typed Programming Languages
- D.53 Structured Programming
- D.54 Suitable Programming Languages
- D.57 Object Oriented Programming
- D.60 Procedural Programming

146.2 GNAT Pro Assurance Toolsuite

146.2.1 Qualification

GNAT Pro compiler family

The GNAT Pro compilers for Ada and for C are qualified at class T3. AdaCore can provide documentation attesting to various aspects such as service history, development standard, and testing results. This documentation has been submitted and accepted in past certification activities. T3 qualification material can also be developed for the GNAT Pro for C++ and GNAT Pro for Rust compilers.

Since compilers are large and complex pieces of software, bugs can be detected (and subsequently corrected) after a particular version has been chosen. Following the requirements stated in 6.7.4.11, however, a corrected version of the compiler cannot be deployed without specific justification. AdaCore offers a dedicated service – GNAT Pro Assurance – on a specified version of the technology, which provides critical problem fixes (or workaround suggestions) as well as detailed descriptions of the changes. Using GNAT Pro Assurance, a customer can integrate a corrected version of a specific compiler release into their development infrastructure without the risk of regressions from unwanted updates.

See *GNAT Pro Assurance* (page 2689).

GNATstack

GNATstack can be qualified as a class T2 tool.

146.2.2 Run-Time Certification

Certification material up to SIL 4 can be developed for the Light and Light-Tasking run-time libraries.

See *Configurable Run-Time Libraries* (page 2689).

146.2.3 Annex D References

- D.10 Data Flow Analysis
- D.15 Coding Standards and Style Guide
- D.18 Equivalence Classes and Input Partition Testing
- D.35 Language Subset

146.3 SPARK Language and Toolsuite

See *SPARK* (page 2687).

146.3.1 Qualification

The SPARK Pro toolsuite can be qualified at class T2.

146.3.2 Annex D References

The SPARK language and toolset can contribute to the deployment or implementation of the following techniques:

- D.2 Analyzable Programs

- D.4 Boundary Value Analysis
- D.10 Data Flow Analysis
- D.14 Defensive Programming
- D.18 Equivalence Classes and Input Partition Testing
- D.24 Failure Assertion Programming
- D.28 Formal Methods
- D.29 Formal Proof
- D.34 Interface Testing
- D.35 Language Subset
- D.38 Modular Approach
- D.57 Object Oriented Programming

146.4 CodeSonar for Ada

See *CodeSonar for Ada* (page 2692).

146.4.1 Defects and Vulnerability Analysis

Qualification

The defects and vulnerability analysis tool in CodeSonar for Ada can be qualified at class T2. It has a long cross-industry track record and has been qualified under other standards in the past, such as DO-178B/C as a verification tool/TQL5.

Annex D References

The defects and vulnerability analysis tool in CodeSonar for Ada can contribute to the deployment or implementation of the following techniques:

- D.2 Analyzable Programs
- D.4 Boundary Value Analysis
- D.8 Control Flow Analysis
- D.10 Data Flow Analysis
- D.14 Defensive Programming
- D.18 Equivalence Classes and Input Partition Testing
- D.24 Failure Assertion Programming
- D.32 Impact Analysis

146.4.2 Basic Static Analysis tools

The basic tools are GNATcheck and GNATmetric.

Qualification

These tools can be qualified at class T2. GNATcheck has been qualified under other standards as well, such as DO-178B/C as a verification tool/TQL5.

Annex D References

- D.2 Analyzable Programs
- D.14 Defensive Programming
- D.15 Coding Standard and Style Guide
- D.35 Language Subset
- D.37 Metrics

146.5 GNAT Dynamic Analysis Suite

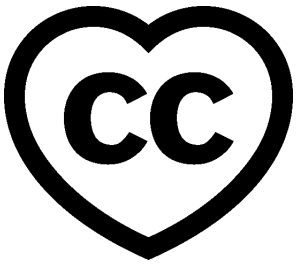
This suite comprises GNATtest, GNATemulator, GNATcoverage, GNATfuzz, and TGEN.

See *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2693).

146.5.1 Qualification

GNATtest, GNATemulator and GNATcoverage can be qualified at class T2. GNATcoverage has been qualified under other standards as well, such as DO-178B/C as a verification tool/TQL5.

146.5.2 Annex D References



- D.50 Structure Based Testing

About the Authors

Benjamin M. Brosgol

Dr. Brosgol is a senior member of the technical staff at AdaCore. He has been involved with programming language design and implementation throughout his career, concentrating on languages and technologies for high-assurance systems. He was a Distinguished Reviewer during the original Ada development, a member of the language design team in the Ada 95 revision, and a member of the Expert Group for the Real-Time Specification for Java under the Java Community Process. He has published dozens of journal articles and delivered conference presentations on topics including the avionics software standard DO - 178C/ED - 12C, the Ada and SPARK languages, real-time software technologies, object-oriented methodologies, and the FACE® (Future Airborne Capabilities Environment) approach to software portability.

Jean-Paul Blanquart

Dr. Blanquart is a recognized authority on computer-based systems safety and dependability, with a decades-long career that spans academic research (LAAS-CNRS, Toulouse, France) and the space industry (Airbus Defence and Space). He was a member of the ECSS Working Groups in charge of revision 1 of ECSS-Q-ST-80C and ECSS-Q-HB-80-03A (and also the dependability and safety standards ECSS-Q-ST-30C and ECSS-Q-ST-40C). He has been an active member of a French cross-domain Working Group on safety and safety standards since its creation in 2010. This Working Group gathers industrial safety experts and related tool providers from domains that include automotive, aviation, defense, nuclear, industrial processes, railway and space.

Foreword

"Failure is not an option"
Gene Kranz (NASA) in the film *Apollo 13*

Software development presents daunting challenges when the resulting system needs to operate reliably, safely, and securely while meeting hard real-time deadlines on a memory-limited target platform. Correct program execution can literally be a matter of life and death, but such is the reality facing developers of space software systems. A project's ability to produce high-assurance software in a cost-effective manner depends on two factors:

- Effective processes for managing the software and system life cycles, with well-defined activities for planning, controlling, and monitoring the work; and
- Effective technologies (programming languages, development and verification tools, version control systems, etc.) to support the software life-cycle processes.

For safety-critical application domains, the first factor is typically anticipated by a regulatory authority in the form of certification / qualification standards such as are found in the civil aviation and nuclear industries. In the space domain the ECSS software-related standards play a similar role, with the current set of documents based on decades of experience with space system development. In particular, the software engineering standard ECSS-E-ST-40C and the software product assurance standard ECSS-Q-ST-80C provide a framework in which software suppliers and customers can interact, with a clear statement and understanding of processes and responsibilities.

Technologies, and more specifically the choice of programming language(s) and supporting toolsuites, directly affect the ease or difficulty of developing, verifying, and maintaining quality software. The state of the art in software engineering has made large strides over the years, with programming language / methodology advances in areas such as modularization and encapsulation. Nevertheless, the key messages have stayed constant:

- The programming language should help prevent errors from being introduced in the first place; and

- If errors are present, the language rules should detect them early in the software life cycle, when defects are easiest and least expensive to correct.

These messages come through clearly in the Ada programming language, which was designed from the start to enforce sound software engineering principles, catching errors early and avoiding pitfalls such as buffer overrun that arise in other languages. Ada has evolved considerably since it first emerged in the mid-1980s, for example adding Object-Oriented Programming support in Ada 95, but each new version has kept true to the original design philosophy.

AdaCore's Ada-based tools have been helping developers design, develop and maintain high-assurance software since the mid 1990s, in domains that include space systems, commercial and military avionics, air traffic control, train systems, automotive, and medical devices. This document summarizes AdaCore's language and tool technologies and shows how they can help space software suppliers meet the requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C. With effective processes as established by these standards, and effective technologies as supplied by AdaCore, software suppliers will be well equipped to meet the challenges of space software development.

November 2021

Foreword to V2.1

In the years since the initial version of this document was published, both ECSS-E-ST-40C and ECSS-Q-ST-80C have been revised, and AdaCore's products have evolved to meet the growing demands for, and challenges to, high assurance in mission-critical real-time software. This new edition reflects the current (2025) versions of ECSS-E-ST-40C, ECSS-Q-ST-80C, and AdaCore's offerings. Among other updates and enhancements to the company's products, the static analysis tools supplementing the GNAT Pro development environment have been integrated into a cohesive toolset (*CodeSonar for Ada*). The dynamic analysis tools have likewise been consolidated, and the resulting *GNAT Dynamic Analysis Suite* has introduced a fuzzing tool — *GNATfuzz* — which exercises the software with invalid input and checks for failsafe behavior.

As editor of this revised edition, I would like to thank my AdaCore colleagues Olivier Appéré and Vasiliy Fofanov, as well as co-author Jean-Paul Blanquart, for their detailed and helpful reviews and suggestions.

For up-to-date information on AdaCore support for developing space software, please visit[712].

CHAPTER

SEVEN

INTRODUCTION

Software for space applications must meet unique and formidable requirements. Hard real-time deadlines, a constrained target execution environment with limited storage capacity, and distributed functionality between ground and on-board systems are some of the challenges, with little margin for error. The software needs to work correctly from the outset, without safety or security defects, and the source code needs to be amenable to maintenance over the system's lifetime (which may extend over decades) as requirements evolve.

To provide a common approach to addressing these challenges, the European Cooperation for Space Standardization (ECSS) was formed in the mid-1990s in a joint effort conducted by the European Space Agency (ESA), individual national space organizations, and industrial partners. As stated in[671]:

> *The European Cooperation for Space Standardization (ECSS) is an initiative established to develop a coherent, single set of user-friendly standards for use in all European space activities.*

The resulting set of standards, available from the ECSS web portal[672], addresses space activities as a whole and complements the relevant country-specific standards.

The ECSS standards specify requirements that must be satisfied (although project-specific tailoring is allowed) and fall into three categories:

- *Space engineering* (the "–E" series),
- *Space product assurance* (the "–Q" series), and
- *Space project management* (the "–M" series).

This document focuses on two specific standards:

- ECSS-E-ST-40C Rev. 1 (Space engineering / Software)[673], and
- ECSS-Q-ST-80C Rev. 2 (Space product assurance / Software product assurance)[674]

and shows how the Ada and SPARK languages, together with AdaCore's product and services offerings, can help space software suppliers comply with these standards. Unless noted otherwise, all references to ECSS-E-ST-40C and ECSS-Q-ST-80C in this document relate to these cited editions of the standards.

AdaCore has a long and successful history supporting developers of space software, and the company has proven experience and expertise in qualification under ECSS-E-ST-40C and ECSS-Q-ST-80C. Examples include:

[671] W. Kriedte and Y. El Gammal. A New Approach to European Space Standards. *ESA Bulletin 81*, February 1995. URL: https://www.esa.int/esapub/bulletin/bullet81/krie81.htm.
[672] European Cooperation for Space Standardization. ECSS Web Portal. URL: https://www.ecss.nl.
[673] *ECSS-E-ST-40C Rev.1 - Software*. ECSS, April 2025. URL: https://ecss.nl/standard/ecss-e-st-40c-rev-1-software-30-april-2025/.
[674] *ECSS-Q-ST-80C Rev.2 - Software product assurance*. ECSS, April 2025. URL: https://ecss.nl/standard/ecss-q-st-80c-rev-2-software-product-assurance-30-april-2025/.

- The ZFP (Zero Footprint) minimal run-time library for Ada on LEON2 ELF, qualified at criticality category B, for the aerospace company AVIO[675].
- The Ravenscar SFP (Small Footprint) QUAL run-time library for Ada on LEON2 and LEON3 boards, prequalified at criticality category B, for ESA[676].

An important update in the 2025 versions of ECSS-E-ST-40C and ECSS-Q-ST-80C is the explicit attention paid to security issues. Memory-safe languages like Ada and SPARK, and formal analysis tools such as SPARK Pro, help reduce the effort in demonstrating security properties in space software.

The remainder of this chapter summarizes the ECSS-E-ST-40C and ECSS-Q-ST-80C standards, and the subsequent chapters have the following content:

- *Programming Languages for Space Software* (page 2751) describes the Ada and SPARK programming languages and relates their software engineering support to the relevant sections / requirements in the two standards.
- Analogously, *Tools for Space Software Development* (page 2765) presents AdaCore's various software development and verification toolsuites and relates their functionality to the relevant sections / requirements in the two standards.
- In the other direction, *Compliance with ECSS-E-ST-40C* (page 2785) surveys the individual requirements in ECSS-E-ST-40C and shows how a large number of them can be met by a software supplier through Ada, SPARK, and/or specific AdaCore products.
- *Compliance with ECSS-Q-ST-80C* (page 2799) does likewise for the requirements in ECSS-Q-ST-80C.
- For ease of reference, the *Abbreviations* (page 2805) chapter contains a table of acronyms and initialisms used in this document, and bibliography lists the various resources cited.

Although this document is focused on specific ECSS standards, the *Programming Languages for Space Software* (page 2751) and *Tools for Space Software Development* (page 2765) chapters explain how the Ada and SPARK languages / technologies and AdaCore's products benefit software development in general for large-scale safety-critical systems. These chapters may thus be applicable to software that has to comply with regulatory standards in other domains.

147.1 ECSS-E-ST-40C: Space engineering / Software

As stated in ECSS-E-ST-40C (Page 2741, 673, p. 11):

> "This Standard covers all aspects of space software engineering including requirements definition, design, production, verification and validation, transfer, operations and maintenance."
>
> "It defines the scope of the space software engineering processes and its interfaces with management and product assurance, which are addressed in the Management (–M) and Product assurance (–Q) branches of the ECSS System, and explains how they apply in the software engineering processes."

ECSS-E-ST-40C defines the following space system software engineering processes:

- Software-related systems requirements process (§ 4.2.2)

[675] AdaCore. Press Release: AVIO Selects AdaCore's GNAT Pro Assurance Toolsuite for European Space Agency Program. January 8, 2019. URL: https://www.adacore.com/press/avio-selects-adacores-gnat-pro-assurance-toolsuite-for-european-space-agency-program.

[676] AdaCore. Press Release: European Space Agency Selects AdaCore's Qualified-Multitasking Solution for Spacecraft Software Development. September 24, 2019. URL: https://www.adacore.com/press/european-space-agency-selects-adacores-qualified-multitasking-solution-for-spacecraft-software-development.

This process links the system and software levels and "establishes the functional and the performance requirements baseline (including the interface requirement specification) (RB) of the software development" (Page 2741, 673, p. 27).

- Software management process (§ 4.2.3)

  This process "tailors the M standards for software-specific issues" and produces "a software development plan including the life cycle description, activities description, milestones and outputs, the techniques to be used, and the risks identification" (Page 2741, 673, pp. 27, 28). It covers the joint review process, interface management, and technical budget and margin management.

- Software requirements and architecture engineering process (§ 4.2.4)

  This process comprises software requirements analysis (based on system requirements) and a resulting software architecture design. Activities associated with the latter include selection of a design method, selection of a computational model for real-time software, description of software behavior, development and documentation of the software interfaces, and definition of methods and tools for software intended for reuse.

- Software design and implementation engineering process (§ 4.2.5)

  This process covers the detailed design of the software items (including an analysis of the dynamic model showing how issues such as storage leakage and corrupted shared data are avoided), coding, testing, and integration.

- Software validation process (§ 4.2.6)

  Software validation entails "software product testing against both the technical specification and the requirements baseline" and "confirm[ing] that the technical specification and the requirements baseline functions and performances are correctly and completely implemented in the final product" (Page 2741, 673, p. 29).

- Software delivery and acceptance process (§ 4.2.7)

  This process "prepares the software product for delivery and testing in its operational environment" (Page 2741, 673, p. 29).

- Software verification process (§ 4.2.8)

  Software verification "confirm[s] that adequate specifications and inputs exist for every activity and that the outputs of the activities are correct and consistent with the specifications and inputs. This process is concurrent with all the previous processes." (Page 2741, 673, p. 30)

- Software operation process (§ 4.2.9)

  This process involves the activities needed to ensure that the software remains operational for its users; these include "mainly the helpdesk and the link between the users, the developers or maintainers, and the customer." (Page 2741, 673, p. 30)

- Software maintenance process (§ 4.2.10)

  This process "covers software product modification to code or associated documentation for correcting an error, a problem or implementing an improvement or adaptation." (Page 2741, 673, p. 31)

- Software security process (§ 4.2.11)

  This process "is supported by a software security analysis that is systematically maintained at different points in the lifecycle of the software.... The software security analysis is used to ensure that security risks are properly addressed.... It is also used to assess and drive the design, implementation and operation of secure software." (Page 2741, 673, p. 32)

The standard specifies the requirements associated with each of these processes and defines the expected output for each requirement. The expected output identifies three entities:

- the relevant destination file,
- the DRL (Document Requirements List) item(s) within that file where the requirement is addressed, and
- the review that will assess whether the requirement is met.

The files in question are the RB (Requirements Baseline), TS (Technical Specification), DDF (Design Definition File), DJF (Design Justification File), MGT (Management File), MF (Maintenance File), OP (Operational Plan), and PAF (Product Assurance File).

The reviews are the SRR (System Requirements Review), PDR (Preliminary Design Review), CDR (Critical Design Review), QR (Qualification Review), AR (Acceptance Review), and ORR (Operational Readiness Review).

The tables below, derived from Table A-1 in Annex A of ECSS-E-ST-40C, show the association between files, DRL items, and reviews. Cells with "E" indicate requirements from ECSS-E-ST-40C, and cells with "Q" are the contributions from ECSS-Q-ST-80C.

147.2 ECSS-Q-ST-80C: Space product assurance / Software product assurance

The ECSS-Q-ST-80C standard defines software product assurance requirements for the development and maintenance of space software systems, including non-deliverable software that affects the quality of the deliverable product. As stated in[Page 2741, 674], p. 20:

> *The objectives of software product assurance are to provide adequate confidence to the customer and to the supplier that the developed or procured/reused software satisfies its requirements throughout the system's lifetime. In particular, that the software is developed to perform properly, securely, and safely in its operational environment, meeting the project's agreed quality objectives.*

The requirements apply throughout the software lifecycle and cover a range of activities, including organizational responsibilities, process assessment, development environment selection, and product verification. The specific set of requirements that need to be met can be tailored based on several factors:

- Dependability and safety aspects, as determined by the software criticality category,
- Software development constraints, for example the type of development (database vs. real-time), or
- Product quality / business objectives as specified by the customer

ECSS-Q-ST-80C defines requirements in the following areas:

- Software product assurance programme implementation

This set of activities includes organizational aspects, product assurance management, risk management and critical item control, supplier selection and control, procurement, tools and supporting environment selection, and assessment and improvement process.

- Software process assurance

  These activities comprise software life cycle management; requirements applicable to all software engineering processes (e.g., documentation, safety analysis, handling of critical software, configuration management, metrics, verification, reuse, and automatic code generation); and requirements applicable to individual software engineering processes or activities (e.g., requirements analysis, architecture and design, coding, testing and validation, delivery and acceptance, operations, and maintenance).

- Software product quality assurance

  These activities comprise product quality objectives and metrication; product quality requirements; software intended for reuse; standard ground hardware and services for operational system; and firmware.

As with ECSS-E-ST-40C, the expected output for each requirement identifies the destination file, the DRL items within that file, and the review(s) that assess compliance with the requirement. The table above includes this information for the requirements in ECSS-Q-ST-80C.

The ECSS standards recognize that software systems (and different components of the same software system) may vary in their effects on system safety. The standards accordingly define several criticality categories, denoted A (most critical) to D, which correspond closely to the software levels in the airborne standard DO - 178C/ED - 12C.

147.3 ECSS Handbooks

Supplementing the normative standards in the –E, –Q, and –M series, ECSS has published a set of handbooks offering additional support, guidance and practical discussion about the standards and their requirements. They indicate how a customer (the organization acquiring the space software or system) will likely interpret the standards and thus how they will expect the supplier to comply.

Several handbooks complement ECSS-E-ST-40C, including:

- ECSS-E-HB-40A (Software engineering handbook)[677],

  This document provides guidance, explanations, and examples on how to satisfy the ECSS-E-ST-40C requirements in practice.

- ECSS-E-HB-40-01A (Agile software development handbook)[678].

  This handbook shows how to reconcile agile development practices with the formal ECSS space software engineering processes.

- ECSS-E-HB-40-02A (Machine learning handbook)[679].

  This handbook provides guidelines on how to create reliable machine learning functions and perform the verification and validation considering the specifics of machine learning development practices.

Several handbooks complement ECSS-Q-ST-80C, including:

[677] *ECSS-E-HB-40A: Space engineering / Software engineering handbook*. ECSS. Noordwijk, The Netherlands; 11 December 2013.
[678] *ECSS-E-HB-40-01A: Space engineering / Agile software development handbook*. ECSS. Noordwijk, The Netherlands; 7 April 2020.
[679] *ECSS-E-HB-40-02A: Space engineering / Machine learning handbook*. ECSS. Noordwijk, The Netherlands; 15 November 2024.

- ECSS-Q-HB-80-01A (Reuse of existing software)[680]

  This handbook offers guidance on software reuse (including software tools) and also presents a Tool Qualification Level (TQL) concept based on DO - 178C/ED - 12C[681], DO - 330/ED - 215[682], and ISO 26262[683].

- ECSS-Q-HB-80-03A Rev. 1 (Software dependability and safety)[684]

  This handbook focuses on analysis techniques such as Failure, Mode and Effects Analysis (FMEA) and their application to software; i.e., how to analyze what happens in case of failure due to software. It covers topics such as defensive programming and prevention of failure propagation.

- ECSS-Q-HB-80-04A (Software metrication program definition and implementation)[685]

  This handbook offers recommendations on organizing and implementing a metrication program for space software projects.

CHAPTER

EIGHT

PROGRAMMING LANGUAGES FOR SPACE SOFTWARE

This chapter explains how space software developers can benefit from the Ada language and its formally analyzable SPARK subset ([686],[687]). Unless explicitly stated otherwise, the Ada discussion applies to the Ada 2012 version of the language standard with Technical Corrigendum 1 ([688],[689],[690]), and the SPARK language discussion applies to the 2014 version of the language as amended by[686]. Both Ada and SPARK support the development and verification of software at the highest criticality class levels.

148.1 Ada

The choice of programming language(s) is one of the fundamental decisions during software design. The source code is the artifact that is developed, verified, and maintained, and it is also the subject of much of the analysis / inspection required for certification / qualification against domain-specific standards. Although in principle almost any programming language can be used for software development, in practice the life-cycle costs for the high-assurance real-time software found in space systems are reduced when the chosen language has been explicitly designed for reliability, safety, security, and ease of maintenance of large, long-lived systems.

Ada helps meet high-assurance requirements through its support for sound software engineering principles, compile-time checks that guarantee type safety, and run-time checks for constraints such as array index bounds and scalar ranges. As will be explained below, the SPARK subset of Ada shares these benefits and adds an important advantage: the dynamic constraints are enforced through mathematics-based static analysis. This avoids run-time overhead for checks in production code while eliminating the risk that such a check could fail. With their standard features for preventing buffer overruns, pointer misuses and other vulnerabilities, Ada and SPARK both serve as memory-safe languages.

148.1.1 Ada language overview

Ada is multi-faceted. From one perspective it is a classical stack-based general-purpose language (unlike languages like Java, it does not require garbage collection), and it is not tied to any specific development methodology. It offers:

- a simple syntax designed for human readability;
- structured control statements;

- flexible data composition facilities;
- strong type checking;
- traditional features for code modularization (“subprograms”);
- standard support for *programming in the large* and module reuse, including packages, Object-Oriented Programming, hierarchical package namespace (*child libraries*), and generic templates;
- a mechanism for detecting and responding to exceptional run-time conditions (*exception handling*); and
- high-level concurrency support (*tasking*) along with a deterministic subset (the Ravenscar profile) appropriate in applications that need to meet high-assurance certification / qualification requirements and/or small footprint constraints.

The language standard also includes:

- an extensive predefined environment with support for I/O, string handling, math functions, containers, and more;
- a standard mechanism for interfacing with other programming languages (such as C and C++); and
- specialized needs annexes for functionality in several domains (Systems Programming, Real-Time Systems, Distributed Systems, Numerics, Information Systems, and High-Integrity Systems).

Source code portability was a key goal for Ada. The challenge for a programming language is to define the semantics in a platform-independent manner but not sacrifice run-time efficiency. Ada achieves this in several ways.

- Ada provides a high-level model for concurrency (tasking), memory management, and exception handling, with standard semantics across all platforms. The language's dynamic semantics can be mapped to the most efficient services provided by the target environment.
- The developer can express the logical properties of a type (such as integer range, floating-point precision, and record fields/types) in a machine-independent fashion, which the compiler can then map to an efficient underlying representation.
- The physical representation of data structures (layout, alignment, and addresses) is sometimes specified by system requirements. Ada allows this to be defined in the program logic but separated from target-independent properties for ease of maintenance.
- Platform-specific characteristics such as machine word size are encapsulated in an API, so that references to these values are through a standard syntax. Likewise, Ada defines a standard type `Address` and associated operations, again facilitating the portability of low-level code.

148.1.2 Ada language background

Ada was designed for large, long-lived applications — and embedded systems in particular — where reliability, maintainability, and efficiency are essential. Under sponsorship of the U.S. Department of Defense, the language was originally developed in the early 1980s (this version is generally known as Ada 83) by a team led by Jean Ichbiah at CII-Honeywell-Bull in France.

Ada was revised and enhanced in an upward-compatible fashion in the early 1990s, under the leadership of Tucker Taft from Intermetrics in the U.S. The resulting language, Ada 95, was the first internationally standardized object-oriented language.

Under the auspices of the International Organization for Standardization (ISO), a further (minor) revision was completed as an amendment to the standard; this version of the language is known as Ada 2005.

Additional features (including support for contract-based programming in the form of subprogram pre- and postconditions and type invariants) were added in Ada 2012, and other enhancements to increase the language's expressiveness were introduced in Ada 2022[691].

The name "Ada" is not an acronym; it was chosen in honor of Augusta Ada Lovelace (1815-1852), a mathematician who is sometimes regarded as the world's first programmer because of her work with Charles Babbage. She was also the daughter of the poet Lord Byron.

The Ada language has long been a language of choice in high-assurance / safety-critical / high-security domains, where software failures can have catastrophic consequences. Ada has a proven track record in space applications, military and commercial aircraft avionics, air traffic control, and railroad software, and it has also seen successful usage in other domains (such as automotive systems and medical devices).

With its embodiment of modern software engineering principles, Ada is especially appropriate for teaching in both introductory and advanced computer science courses, and it has also been the subject of significant research, especially in the area of real-time technologies. Throughout much of Ada's history, a worldwide group of experts from industry, academia, and government convened a biannual meeting — the *International Real-Time Ada Workshop* (*IRTAW*) — to focus on Ada's support for real-time software. The 1997 IRTAW in Ravenscar, UK, led directly to the definition of a subset of Ada's concurrency features with deterministic semantics — the so-called *Ravenscar Profile*[692]. This work broke new ground in supporting the use of concurrent programming in high-assurance software.

AdaCore has a long history and close connection with the Ada programming language. Company members worked on the original Ada 83 design and review and played key roles in the Ada 95 project as well as the subsequent revisions. The initial GNAT compiler was delivered at the time of the Ada 95 language's standardization, thus guaranteeing that users would have a quality implementation for transitioning to Ada 95 from Ada 83 or other languages.

The following subsections provide additional detail on Ada language features.

148.1.3 Scalar ranges

Unlike languages based on C (such as C++, Java, and C#), Ada allows the programmer to simply and explicitly specify the range of values that are permitted for variables of scalar types (integer, floating-point, fixed-point, and enumeration types). The attempted assignment of an out-of-range value raises an exception, reflecting a run-time error.

The ability to specify range constraints makes the programmer's intent explicit and makes it easier to detect a major source of coding and user input errors. It also provides useful information to static analysis tools and facilitates automated proofs of program properties.

Here's an example of an integer scalar range and an associated run-time check:

```
declare
   My_Score : Integer range 1..100;
   N        : Integer;
begin
   ...  -- Code that assigns an integer value to N
```

(continues on next page)

[691] ISO/IEC JTC1/SC22. *Ada Reference Manual, 2022 Edition, Language and Standard Libraries*. International Organization for Standardization, 2022. URL: https://www.adacore.com/documentation/ada-2022-reference-manual.

[692] Alan Burns, Brian Dobbing and Tullio Vardanega. Guide for the use of the Ada Ravenscar Profile in high integrity systems. Technical Report YCS-2003-348, University of York, January 2003. URL: https://www.open-std.org/jtc1/sc22/wg9/n424.pdf.

(continued from previous page)

```
   My_Score := N;
   -- A run-time check verifies that N is within the range 1 through 100, inclusive
   -- If this check fails, the Constraint_Error exception is raised
end;
```

The run-time check can be optimized out if the compiler can guarantee that the value of `N` is within the range 1 through 100 when control reaches the assignment to `My_Score`.

148.1.4 Contract-based programming

A feature introduced in Ada 2012 allows extending a subprogram specification or a type/subtype declaration with a contract (a Boolean assertion). Subprogram contracts take the form of preconditions and postconditions; type contracts are used for invariants; and subtype contracts provide generalized constraints (predicates). Through contracts the developer can formalize the intended behavior of the application, and can verify this behavior by testing, static analysis or formal proof.

Here's a skeletal example that illustrates contract-based programming; a `Table` object is a fixed-length container for distinct **`Float`** values.

```
package Table_Pkg is
   type Table is private;  -- Encapsulated type

   function Is_Full  (T    : in Table) return Boolean;

   function Contains (T    : in Table;
                      Item : in Float) return Boolean;

   procedure Insert (T : in out Table; Item: in Float)
     with Pre  => not Is_Full(T) and
                  not Contains(T, Item),
          Post => Contains(T, Item);

   procedure Remove (T : in out Table; Item: in Float);
     with Pre  => Contains(T, Item),
          Post => not Contains(T, Item);
   ...
private
   ... -- Full declaration of Table
end Table_Pkg;

package body Table_Pkg is
   ... -- Implementation of Is_Full, Contains, Insert, Remove
end Table_Pkg;
```

A compiler option controls whether the pre- and postconditions are checked at run time. If checks are enabled, any pre- or postcondition failure — i.e., the contract's Boolean expression evaluating to **`False`** — raises the `Assertion_Error` exception.

Ada's type invariants and type / subtype predicates specify precisely what is and is not valid for any particular (sub)type, including composite types such as records and arrays. For example, the code fragment below specifies that field `Max_Angle` in the `Launching_Pad` structure below is the maximal angle allowed, given the distance `D` to the center of the launching pad and the height `H` of the rocket. The compiler will insert the necessary run-time checks when a `Launching_Pad` object is created, to verify this predicate as well as the constraints on the individual fields:

```
subtype Meter  is Float range 0.0 .. 200.0;
subtype Radian is Float range 0.0 .. 2.0 * Pi;
```

(continues on next page)

(continued from previous page)

```
type Launching_Pad is
   record
      D, H      : Meter;
      Max_Angle : Radian;
   end record
with
   Predicate => Arctan (H, D) <= Max_Angle;
```

Further information about type invariants and type / subtype predicates may be found in the *Design by contracts* chapter of the *Introduction to Ada* course of[693].

148.1.5 Programming in the large

The original Ada 83 design introduced the package construct, a feature that supports encapsulation (*information hiding*) and modularization, and which allows the developer to control the namespace that is accessible within a given compilation unit. Ada 95 introduced the concept of *child units*, which provides a hierarchical and extensible namespace for library units and thus eases the design and maintenance of very large systems.

Ada 2005 extended the language's modularization facilities by allowing mutual references between package specifications, thus making it easier to interface with languages such as Java.

148.1.6 Generic templates

A key to reusable components is a mechanism for parameterizing modules with respect to data types and other program entities. A typical example is a data structure (e.g., a stack, FIFO queue, or varying-length array) for an arbitrary element type T, where each element of the data structure is of type T. For safety and efficiency, compile-time checks should enforce type safety both within the parameterized module, and at each use (*instantiation*). Conceptually, an instantiation can be regarded as an expansion of the parameterized module, with actual parameters replacing the formal parameters. However, the expansion is not at the lexical/syntactic level (source text) but rather at the semantic level (scope-resolved names). In addition, an implementation may be able to share a single copy of the code across multiple instantiations and thereby save code space.

Ada supplies this functionality through a facility known as *generics*, with type consistency enforced by the compiler both within the generic unit and at each instantiation. Ada generics are analogous to C++ templates but with more extensive compile-time checking: a data object within a generic unit can only be processed using operations that are known to be available for the object's type. (As a historical note, at the ACM SIGPLAN Conference on History of Programming Languages in 1993, the C++ designer Bjarne Stroustrup acknowledged the Ada design for generics as one of the inspirations for templates in C++[694].)

148.1.7 Object-Oriented Programming (OOP)

Ada 83 was object-based, allowing the partitioning of a system into modules (packages) corresponding to abstract data types or abstract objects. Full OOP support was not provided since, first, it seemed not to be required in the real-time domain that was Ada's primary target, and second, the apparent need for automatic garbage collection in an object-oriented language would have interfered with predictable and efficient performance.

However, large real-time systems often have components such as graphical user interfaces (GUIs) that do not have hard real-time constraints and that can be most effectively developed using OOP features. In part for this reason, Ada 95 added comprehensive support

[693] AdaCore. Online training for Ada and SPARK. URL: https://learn.adacore.com/.
[694] Association for Computing Machinery (ACM). *HOPL-II: The Second ACM SIGPLAN Conference on History of Programming Languages*, 1993. URL: https://dl.acm.org/doi/proceedings/10.1145/154766.

for OOP, through its *tagged type* facility: classes, polymorphism, inheritance, and dynamic binding. These features do not require automatic garbage collection; instead, definitional features introduced by Ada 95 allow the developer to supply type-specific storage reclamation operations (*finalization*).

Ada 2005 brought additional OOP features, including Java-like interfaces and traditional `X.P(...)` notation for invoking operation `P(...)` on object X.

Ada is methodologically neutral and does not impose a distributed overhead for OOP. If an application does not need OOP, then the OOP features do not have to be used, and there is no run-time penalty.

See[Page 2751, 689] or[695] for more details.

148.1.8 Concurrent programming

Ada supplies a structured, high-level facility for concurrency. The unit of concurrency is a program entity known as a *task*. Tasks can communicate implicitly via shared data or explicitly via a synchronous control mechanism known as the rendezvous. A shared data item can be defined abstractly as a *protected object* (a feature introduced in Ada 95), with operations executed under mutual exclusion when invoked from multiple tasks. Protected objects provide the functionality of semaphores and condition variables but more clearly and reliably (e.g., avoiding subtle race conditions).

Ada supports asynchronous task interactions for timeouts, software event notifications, and task termination. Such asynchronous behavior is deferred during certain operations, to prevent the possibility of leaving shared data in an inconsistent state. Mechanisms designed to help take advantage of multicore architectures were introduced in Ada 2012.

148.1.9 Systems programming

Both in the core language and the Systems Programming Annex, Ada supplies the necessary features for low-level / hardware-specific processing. For example, the programmer can specify the bit layout for fields in a record, define alignment and size properties, place data at specific machine addresses, and express specialized code sequences in assembly language. Interrupt handlers can also be written in Ada, using the protected object facility.

148.1.10 Real-time programming

Ada's tasking facility and the Real-Time Systems Annex support common idioms such as periodic or event-driven tasks, with features that can help avoid unbounded priority inversions. A protected object locking policy is defined that uses priority ceilings; this has an especially efficient implementation in Ada (mutexes are not required) since protected operations are not allowed to block. Ada 95 defined a standard task dispatching policy in which a task runs until blocked or preempted, and Ada 2005 introduced several others including Earliest Deadline First.

148.1.11 Time and Space Analysis

Timing verification

Suitably subsetted, Ada (and SPARK) are amenable to the static analysis of timing behavior. This kind of analysis is relevant for real-time systems, where worst-case execution time (WCET) must be known in order to guarantee that timing deadlines will always be met. Timing analysis is also of interest for secure systems, where the issue might be to show that programs do not leak information via so-called side-channels based on the observation of differences in execution time.

[695] *High-Integrity Object-Oriented Programming in Ada, Version 1.4*. AdaCore, October 2016. URL: https://www.adacore.com/knowledge/technical-papers/high-integrity-oop-in-ada/.

AdaCore does not produce its own WCET tool, but there are several such tools on the market from partner companies, such as RapiTime from Rapita Systems Ltd.

Memory usage verification

Ada and SPARK can support the static analysis of worst-case memory consumption, so that a developer can show that a program will never run out of memory at execution time.

In both SPARK and Ada, users can specify pragma `Restrictions` with the standard arguments `No_Allocators` and `No_Implicit_Heap_Allocations`. This will completely prevent heap usage, thus reducing memory usage analysis to a worst-case computation of stack usage for each task in a system. Stack size analysis is implemented directly in AdaCore's GNATstack tool, as described in *GNATstack* (page 2772).

148.1.12 High-integrity systems

With its emphasis on sound software engineering principles, Ada supports the development of safety-critical and other high-integrity applications, including those that need to be certified/qualified against software standards such as ECSS-E-ST-40C and ECSS-Q-ST-80C for space systems, DO - 178C/ED - 12C for avionics[696], and CENELEC EN 50128 for rail systems[697]. Similarly, Ada (and its SPARK subset) can help developers produce high Evaluation Assurance Level (EAL) code that meets security standards such as the Common Criteria[698]. Key to Ada's support for high-assurance software is the language's memory safety; this is illustrated by a number of features, including:

- Strong typing

  Data intended for one purpose will only be accessed via operations that are legal for that data item's type, so errors such as treating pointers as integers (or vice versa) are prevented. (Low-level code sometimes needs to defeat the language's type checking; e.g., by treating *raw bits* as a value of a specific type. As a language that supports systems programming, Ada allows such usages but requires explicit syntax that makes the intent clear.)

- Array bounds checking

  A run-time check guarantees that an array index is within the bounds of the array. This prevents buffer overrun vulnerabilities that are common in C and C++. In many cases a compiler optimization can detect statically that the index is within bounds and thus eliminate any run-time code for the check.

- Prevention of null pointer dereferences

  As with array bounds, pointer dereferences are checked to make sure that the pointer is not null. Again, such checks can often be optimized out.

- Prevention of dangling references

  A scope accessibility check ensures that a pointer (known in Ada as an *access value*) cannot reference an object on the stack after exit/return from the scope (block or subprogram) in which the object is declared. Such checks prevent dangling references to stack objects (i.e., subprogram parameters and local variables) and are generally static, with no run-time overhead. (Since Ada does not require garbage collection of inaccessible dynamically allocated objects, it provides an `Unchecked_Deallocation` facility for programmer-supplied deallocation. Uses of this feature require explicit syntax — a `with` clause at the beginning of the compilation unit. This makes clear that

[696] *DO-178C/ED-12C: Software Considerations in Airborne Systems and Equipment Certification*. RTCA and EUROCAE, December 2011.
[697] *EN 50128/A2: Railway applications – Communications, signalling and processing systems – Software for railway control and protection systems*. CENELEC, July 2020.
[698] *Common Criteria for Information Technology Security Evaluation (ISO/IEC 15408)*. Common Criteria Development Board, 2022. URL: https://www.commoncriteriaportal.org/.

special attention needs to be paid to verification, since erroneous deallocations can lead to dangling references.)

The evolution of Ada has seen a continued increase in support for safety-critical and high-security applications. Ada 2005 standardized the Ravenscar Profile[Page 2753, 692], a collection of concurrency features that are powerful enough for real-time programming but simple enough to make safety certification practical. Ada 2012 introduced contract-based programming facilities, allowing the programmer to specify preconditions and/or postconditions for subprograms, and invariants for encapsulated (private) types. These can serve both for run-time checking and as input to static analysis tools.

The most recent version of the standard, Ada 2022, has added several contract-based programming constructs inspired by SPARK (`Contract_Cases`, `Global`, and `Depends` aspects) and, more generally, has enhanced the language's expressiveness. For example, Ada 2022 has introduced some new syntax in its concurrency support and has defined the Jorvik tasking profile, which is more inclusive than Ravenscar.

148.1.13 Enforcing a coding standard

Ada is a large language, suitable for general-purpose programming, but the full language may be inappropriate in a safety- or security-critical application. The generality and flexibility of some features — especially those with complex run-time semantics — complicate analysis and could interfere with traceability / certification requirements or impose too large a memory footprint. A project will then need to define and enforce a coding standard that prohibits problematic features. Several techniques are available:

- pragma `Restrictions`

  This standard Ada pragma allows the user to specify constructs that the compiler will reject. Sample restrictions include dependence on particular packages or language facilities, or usage of features requiring unwanted implementation techniques (e.g. run-time support that is overly complex and difficult to certify).

- pragma `Profile`

  This standard Ada pragma provides a common name for a collection of related `Restrictions` pragmas. The predefined pragma `Profile(Ravenscar)` is a shorthand for the various restrictions that comprise the Ravenscar tasking subset.

- Static analysis tool (coding standard enforcer)

  Other restrictions on Ada features can be detected by AdaCore's automated GNATcheck tool (see *GNATcheck* (page 2778)) that is included with CodeSonar for Ada. The developer can configure this rule-based and tailorable tool to flag violations of the project's coding standard, such as usage of specific prohibited types or subprograms defined in otherwise-permitted packages.

148.1.14 Ada and the ECSS Standards

ECSS-E-ST-40C covers software engineering practice, and ECSS-Q-ST-80C covers software product assurance, and both of these areas are *sweet spots* that match Ada's strengths. Please see *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799) to learn how specific clauses in these standards relate to individual Ada features. In summary, the use of Ada can help the software supplier meet the requirements in the following sections:

- ECSS-E-ST-40C
  - §5.4 Software requirements and architecture engineering process
    - §5.4.3 Software architecture design
  - §5.5 Software design and implementation engineering process

        * §5.5.2 Design of software items
    - §5.8 Software verification process
        * §5.8.3 Verification activities
    - §5.9 Software operation process
        * §5.9.4 Software operation support
    - §5.10 Software maintenance process
        * §5.10.4 Modification implementation
    - §5.11 Software security process
        * § 5.11.2 Process implementation
        * § 5.11.3 Software security analysis
        * § 5.11.5 Security activities in the software life cycle
    - Annex U - Software code verification
- ECSS-Q-ST-80C
    - §6.2 Requirements applicable to all software engineering processes
        * §6.2.3 Handling of critical software
        * §6.2.9 Software security
        * §6.2.10 Handling of security sensitive software
    - §6.3 Requirements applicable to individual software engineering processes or activities
        * §6.3.4 Coding
    - §7.2 Product quality requirements
        * §7.2.2 Design and related documentation

In brief, Ada is an internationally standardized language combining object-oriented programming features, well-engineered concurrency facilities, real-time predictability and performance, and built-in reliability through both compile-time and run-time checks. With its support for producing software that is correct, maintainable, and efficient, the language is especially well suited for writing space applications.

148.2 SPARK

148.2.1 SPARK Basics

SPARK (Page 2751, 686, Page 2751, 687) is a software development technology (programming language and verification toolset) specifically oriented around applications demanding an ultra-low defect level, for example where safety and/or security are key requirements. SPARK Pro is the commercial-grade offering of the SPARK technology developed by AdaCore, Capgemini Engineering (formerly Altran), and Inria. As will be described in *Static Verification: SPARK Pro* (page 2766), the main component in the toolset is GNATprove, which performs formal verification on SPARK code.

SPARK has an extensive industrial track record. Since its inception in the late 1980s it has been used worldwide in a wide variety of applications, including civil and military avionics, space satellite control, air traffic management / control, railway signaling, cryptographic software, medical devices, automotive systems, and cross-domain solutions. SPARK 2014 is the most recent version of the technology.

The SPARK language has been stable over the years, with periodic enhancements. The 2014 version of SPARK represented a major revision, incorporating contract-based programming syntax from Ada 2012, and subsequent upgrades included support for pointers (access types) based on the Rust ownership model.

The SPARK language is a large subset of Ada 2012 and is memory safe. It includes as much of the Ada language as is possible / practical to analyze formally, while eliminating sources of undefined and implementation-dependent behavior. SPARK includes Ada's program structure support (packages, generics, child libraries), most data types, safe pointers, contract-based programming (subprogram pre- and postconditions, scalar ranges, type/subtype predicates), Object-Oriented Programming, and the Ravenscar subset of the tasking features.

Principal exclusions are side effects in functions and expressions, problematic aliasing of names, exception handling, pointer functionality that may be unsafe, and most tasking features.

A legal SPARK program has unambiguous semantics: its effect is precisely defined and does not depend on the implementation. This property helps ensure the soundness of static verification; i.e., the absence of *false negatives*. If the SPARK tools report that a program does not have a specific vulnerability, such as a reference to an uninitialized variable, then that conclusion can be trusted with mathematical certainty. Soundness builds confidence in the tools, provides evidence-based assurance, completely removes many classes of dangerous defects, and significantly simplifies subsequent verification effort (e.g., testing), owing to less rework. Moreover, the SPARK tools achieve soundness while keeping *false positives* manageable.

SPARK offers the flexibility of configuring the language on a per-project basis. Restrictions can be fine-tuned based on the relevant coding standards or run-time environments.

SPARK code can easily be combined with full Ada code or with C, so that new systems can be built on and reuse legacy codebases. Moreover, the same code base can have some sections in SPARK and others excluded from SPARK analysis (SPARK and non-SPARK code can also be mixed in the same package or subprogram).

Software verification typically involves extensive testing, including unit tests and integration tests. Traditional testing methodologies are a major contributor to the high delivery costs for safety-critical software. Furthermore, testing can never be complete and thus may fail to detect errors. SPARK addresses this issue by using automated proof (embodying mathematics-based formal methods) to demonstrate program integrity properties up to functional correctness at the subprogram level, either in combination with or as a replacement for unit testing. In the high proportion of cases where proofs can be discharged automatically, the cost of writing unit tests may be completely avoided. Moreover, verification by proofs covers all execution conditions and not just a sample.

Here is an example of SPARK code:

```
package Example is
   N : Positive := 100; -- N constrained to 1 .. Integer'Last

   procedure Decrement (X in out Integer)
      with Global => (Input => N),
           Depends => (X => (X, N)),
           Pre     => X >= Integer'First + N,
           Post    => X = X'Old - N;
end Example;

package body Example is
   procedure Decrement (X in out Integer) is
   begin
      X := X - N;
   end Decrement;
end Example;
```

The `with` constructs, known as *aspects*, here define the `Decrement` procedure's contracts:

- `Global`: the only access to non-local data is to read the value of `N`
- `Depends`: the value of `X` on return depends only on `N` and the value of `X` on entry
- `Pre`: a Boolean condition that the procedure assumes on entry
- `Post`: a Boolean condition that the subprogram guarantees on return

In this example the SPARK tool can verify the `Global` and `Depends` contracts and can also prove several dynamic properties: no run-time errors will occur during execution of the `Decrement` procedure, and, if the `Pre` contract is met when the procedure is invoked then the `Post` contract will be satisfied on return.

SPARK (and the SPARK proof tools) work with Ada 2012 syntax, but a SPARK program can also be expressed in Ada 95, with contracts captured as pragmas.

148.2.2 Ease of Adoption

User experience has shown that the language and the SPARK Pro toolset do not require a steep learning curve. Training material such as AdaCore's online AdaLearn course for SPARKPage 2755, 693 can quickly bring developers up to speed; users are assumed to be experts in their own application domain such as space technology and do not need to be familiar with formal methods or the proof approaches implemented by the toolset. In effect, SPARK Pro is an advanced static analysis tool that will detect many logic errors and security vulnerabilities very early in the software life cycle. It can be smoothly integrated into an organization's existing development and verification methodology and infrastructure.

SPARK uses the standard Ada 2012 contract syntax, which both simplifies the learning process and also allows new paradigms of software verification. Programmers familiar with writing executable contracts for run-time assertion checking can use the same approach but with additional flexibility: the contracts can be verified either dynamically through classical run-time testing methods or statically (i.e., pre-compilation and pre-test) using automated tools.

148.2.3 Levels of Adoption of Formal Methods

Formal methods are not an *all or nothing* technique. It is possible and in fact advisable for an organization to introduce the methodology in a stepwise manner, with the ultimate level depending on the assurance requirements for the software. This approach is documented in[699], which details the levels of adoption, including the benefits and costs at each level, based on the practical experience of a major aerospace company in adopting formal methods incrementally; the development team did not have previous knowledge of formal methods. The levels are additive; all the checks at one level are also performed at the next higher level.

Stone level: Valid SPARK

As the first step, a project can implement as much of the code as is possible in the SPARK subset, run the SPARK analyzer on the codebase (or new code), and look at violations. For each violation, the developer can decide whether to convert the code to valid SPARK or exclude it from analysis. The benefits include easier maintenance for the SPARK modules (no aliasing, no side effects in functions) and project experience with the basic usage of formal methods. The costs include the effort that may be required to convert the code to SPARK (especially if there is heavy use of pointers).

[699] *Implementation Guidance for the Adoption of SPARK, Release 1.2*. AdaCore and Thales. July 24, 2020. URL: https://www.adacore.com/books/implementation-guidance-spark.

Bronze level: Initialization and correct data flow

This level entails performing flow analysis on the SPARK code to verify intended data usage. The benefits include assurance of no reads of uninitialized variables, no interference between parameters and global objects, no unintended access to global variables, and no race conditions on accesses to shared data. The costs include a conservative analysis of arrays (since indices may be computed at run time) and potential *false alarms* that need to be inspected.

Silver level: Absence of run-time errors (AORTE)

At the Silver level, the SPARK proof tool performs flow analysis, locates all potential run-time checks (e.g., array indexing), and then attempts to prove that none will fail. If the proof succeeds, this brings all the benefits of the Bronze level plus the ability to safely compile the final executable without exception checks. Critical software should aim for at least this level. The cost is the additional effort needed to obtain provability. In some cases (if the programmer knows that an unprovable check will always succeed, for example because of hardware properties) it may be necessary to augment the code with pragmas to help the prover.

Gold level: Proof of key integrity properties

At the Gold level, the proof tool will verify properties such as correctness of critical data invariants or safe transitions between program states. Subprogram pre- and postconditions and subtype predicates are especially useful here, as is *ghost* code that serves only for verification and is not part of the executable. A benefit is that the proofs can be used for safety case rationale, to replace certain kinds of testing. The cost is increased time for tool execution, and the possibility that some properties may be beyond the abilities of current provers.

Platinum level: Full functional correctness

At the Platinum level, the algorithmic code is proved to satisfy its formally specified functional requirements. This is still a challenge in practice for realistic programs but may be appropriate for small critical modules, especially for security-critical systems at high Evaluation Assurance Levels where formal methods can provide the needed confidence.

148.2.4 Hybrid Verification

Hybrid verification combines formal methods with traditional testing. A typical scenario is an in-progress project that is based on testing but which has high-assurance requirements that can best be demonstrated through formal methods. The new code will be in SPARK; and the adoption level depends on the experience of the project team (typically Stone at the start, then progressing to Bronze or Silver). The existing codebase may be in Ada or other languages. To maximize the precision of the SPARK analysis, the subprograms that the SPARK code will be invoking should have relevant pre- and postconditions expressing the subprograms' low-level requirements. If the non-SPARK code is not in Ada, then the pre- and postconditions should be included on the Ada subprogram specification corresponding to the imported function; here is an example.

```
function getascii return Interfaces.C.unsigned_char
   with Post => getascii'Result in 0..127;

pragma Import (C, getascii);
-- Interfaces.C.unsigned_char is a modular (unsigned)
-- integer type, typically ranging from 0 through 255

procedure Example is
```

(continues on next page)

(continued from previous page)

```
   N : Interfaces.C.unsigned_char range 0 .. 127;
begin
   N := getascii;
   -- SPARK can prove that no range check is needed
end Example;
```

The verification activity depends on whether the formally verified code invokes the tested code or vice versa.

- The SPARK code calls a tested subprogram

  If the tested subprogram has a precondition, the SPARK code is checked at each call site to see if the precondition is met. Any call that the proof tool cannot verify for compliance with the precondition needs to be inspected to see why the precondition cannot be proved. It could be a problem with the precondition, a problem at the call site, or a limitation of the prover.

  The postcondition of the called subprogram can be assumed to be valid at the point following the return, although the validity needs to be established by testing. In the example above, testing would need to establish that the `getascii` function only returns a result in the range 0 through 127.

- The SPARK code is invoked from tested code

  Testing would need to establish that, at each call, the precondition of the SPARK subprogram is met. Since the SPARK subprogram has been formally verified, at the point of return the subprogram's postcondition is known to be satisfied. Testing of the non-SPARK code can take advantage of this fact, thereby reducing the testing effort.

Hybrid verification can be performed within a single module; e.g., a package can specify different sections where SPARK analysis is or is not to be performed.

148.2.5 SPARK and the ECSS Standards

In summary, the qualities that make Ada an appropriate choice for space software also apply to SPARK (see *Ada and the ECSS Standards* (page 2758)). And specific to SPARK, the static determination that the code is free from run-time errors ("Silver" level of SPARK adoption) can significantly reduce the effort in showing that the application is sufficiently safe and secure.

The use of SPARK can help the software supplier meet the requirements in the following sections of ECSS-E-ST-40C and ECSS-Q-ST-80C:

- ECSS-E-ST-40C
  - §5.4 Software requirements and architecture engineering process
    - §5.4.3 Software architecture design
  - §5.5 Software design and implementation engineering process
    - §5.5.2 Design of software items
  - §5.8 Software verification process
    - §5.8.3 Verification activities
  - §5.10 Software maintenance process
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - § 5.11.2 Process implementation
    - § 5.11.3 Software security analysis

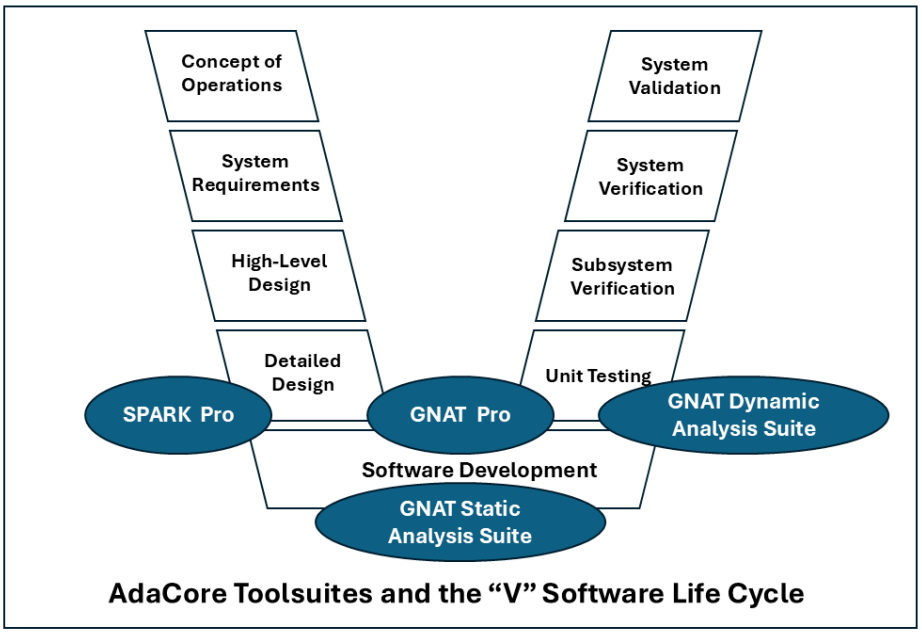
        * § 5.11.5 Security activities in the software life cycle
    - Annex U Software code verification
- ECSS-Q-ST-80C
    - §6.2 Requirements applicable to all software engineering processes
        * §6.2.3 Handling of critical software
        * §6.2.9 Software security
        * §6.2.10 Handling of security sensitive software
    - §6.3 Requirements applicable to individual software engineering processes or activities
        * §6.3.4 Coding
    - §7.2 Product quality requirements
        * §7.2.2 Design and related documentation

Note in particular that the SPARK language directly addresses several criteria in ECSS-Q-ST-80C requirement 6.2.3.2a:

- "use of a 'safe subset' of programming language"
- "use of formal design language for formal proof"

Further details on how SPARK and SPARK Pro can contribute to compliance with the ECSS standards are presented in *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799).

CHAPTER



NINE

TOOLS FOR SPACE SOFTWARE DEVELOPMENT

This chapter explains how suppliers of space software can benefit from AdaCore's products. The advantages stem in general from reduced life cycle costs for developing and verifying high-assurance software. More specifically, in connection with space software qualification, several tools can help to show that an application complies with the requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C.

149.1 AdaCore Tools and the Software Life Cycle

The software life cycle is often depicted as a *V* diagram, and the figure below shows how AdaCore's major products fit into the various stages. Although the stages are rarely performed as a single sequential process — the phases typically involve feedback / iteration, and requirements often evolve as a project unfolds — the *V* chart is useful in characterizing the various kinds of activities that occur.

AdaCore Toolsuites and the "V" Software Life Cycle

As can be seen in the figure, AdaCore's toolsuites apply towards the bottom of the *V*. In summary:

- The SPARK Pro static analysis toolsuite (see *Static Verification: SPARK Pro* (page 2766)) applies during Detailed Design and Software Development. It includes a proof tool that verifies properties ranging from correct information flows to functional correctness.

- The GNAT Pro development environment (see *GNAT Pro Development Environment* (page 2769)) applies during Detailed Design, Software Development, and Unit Testing. It consists of gcc-based program build tools, an integrated and tailorable graphical user interface, accompanying tools, and a variety of supplemental libraries (including some for which qualification material is available for ECSS-E-ST-40C and ECSS-Q-ST-80C.)
- CodeSonar for Ada (see *Static Verification: CodeSonar for Ada* (page 2776)) applies during Software Development. It contains a variety of tools for Ada, including a vulnerability detector that can be used retrospectively to detect issues in existing codebases and/or during new projects to prevent errors from being introduced.
- The GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) applies during Software Development and Unit Testing. One of these tools, GNATcoverage, supports code coverage and reporting at various levels of granularity for both Ada and C. It can be used during unit and integration testing.

The following sections describe the tools in more detail and show how they can assist in developing and verifying space system software.

149.2 Static Verification: SPARK Pro

SPARK Pro is an advanced static analysis toolsuite for the SPARK subset of Ada, bringing mathematics-based confidence to the verification of critical code. Built around the GNATprove formal analysis and proof tool, SPARK Pro combines speed, flexibility, depth and soundness, while minimizing the generation of *false alarms*. It can be used for new high-assurance code (including enhancements to or hardening of existing codebases at lower assurance levels, written in full Ada or other languages such as C) or projects where the existing high-assurance coding standard is sufficiently close to SPARK to ease transition.

149.2.1 Powerful Static Verification

The SPARK language supports a wide range of static verification techniques. At one end of the spectrum is basic data- and control-flow analysis; i.e., exhaustive detection of errors such as attempted reads of uninitialized variables, and ineffective assignments (where a variable is assigned a value that is never read). For more critical applications, dependency contracts can constrain the information flow allowed in an application. Violations of these contracts — potentially representing violations of safety or security policies — can then be detected even before the code is compiled.

In addition, SPARK supports mathematical proof and can thus provide high confidence that the software meets a range of assurance requirements: from the absence of run-time exceptions, to the enforcement of safety or security properties, to compliance with a formal specification of the program's required behavior.

As described earlier (see *Levels of Adoption of Formal Methods* (page 2761)), the SPARK technology can be introduced incrementally into a project, based on the assurance requirements. Each level, from Bronze to Platinum, comes with associated benefits and costs.

149.2.2 Minimal Run-Time Footprint

Developers of systems with security requirements are generally advised to "minimize the trusted computing base", making it as small as possible so that high-assurance verification is feasible. However, adhering to this principle may be difficult if a Commercial Off-the-Shelf (COTS) library or operating system is used: how are these to be evaluated or verified without the close (and probably expensive) cooperation of the COTS vendor?

For the most critical embedded systems, SPARK supports the so-called *Bare-Metal* development style, where SPARK code is running directly on a target processor with little or no COTS libraries or operating system at all. SPARK is also designed to be compatible with

GNAT Pro's Light run-time library. In a Bare-Metal / light run-time development, every byte of object code can be traced to the application's source code and accounted for. This can be particularly useful for systems that must undergo evaluation by a national technical authority or regulator.

SPARK code can also run with a specialized run-time library on top of a real-time operating system (RTOS), or with a full Ada run-time library and a commercial desktop operating system. The choice is left to the system designer, not imposed by the language.

149.2.3 CWE Compatibility

SPARK Pro detects a number of dangerous software errors in The MITRE Corporation's Common Weakness Enumeration (CWE), and the tool has been certified by the MITRE Corporation as a "CWE-Compatible" product[700].

The table below lists the CWE weaknesses detected by SPARK Pro:

Table 38: SPARK Pro and the CWE

CWE Weakness	Description
CWE 119, 120, 123, 126, 127, 129, 130,	Buffer overflow/underflow
CWE 136, 137	Variant record field violation, Use of incorrect type in inheritance hierarchy
CWE 188	Reliance on data layout
CWE 190, 191	Numeric overflow/underflow
CWE 193	Off-by-one error
CWE 194	Unexpected sign extension
CWE 197	Numeric truncation error
CWE 252, 253	Unchecked or incorrectly checked return value
CWE 366	Race Condition
CWE 369	Division by zero
CWE 456, 457	Use of uninitialized variable
CWE 466, 468, 469	Pointer errors
CWE 476	Null pointer dereference
CWE 562	Return of stack variable address
CWE 563	Unused or redundant assignment
CWE 682	Range constraint violation
CWE 786, 787, 788,	Buffer access errors
CWE 820	Missing synchronization
CWE 821	Incorrect synchronization
CWE 822, 823, 824,	Pointer errors
CWE 835	Infinite loop

149.2.4 SPARK Pro and the ECSS Standards

SPARK Pro can help a space software supplier in various ways. At a general level, the technology supports the development of analyzable and portable code:

- The tool enforces a number of Ada restrictions that are appropriate for high-assurance software. For example, the use of tasking constructs outside the Ravenscar subset will be flagged.
- The full Ada language has several implementation dependencies that can result in the same source program yielding different results when compiled by different compilers.

[700] The MITRE Corp. CWE-Compatible Products and Services. URL: https://cwe.mitre.org/compatible/compatible.html.

For example, the evaluation order in expressions is not specified, and different orderings may produce different values if one of the terms has a side effect. (A detailed discussion of this issue and its mitigation may be found in[701].) Such implementation dependencies are either prohibited in SPARK and thus detected by SPARK Pro, or else they do not affect the computed result. In either case the use of SPARK Pro eases the effort in porting the code from one environment to another.

More specifically, using the SPARK Pro technology can help the supplier meet ECSS-E-ST-40C and ECSS-Q-ST-80C requirements in a number of areas. These comprise the ones mentioned earlier (see *SPARK and the ECSS Standards* (page 2763)) that relate to the SPARK language, together with the following:

- ECSS-E-ST-40C
  - §5.4 Software requirements and architecture engineering process
    - §5.4.3 Software architecture design
  - §5.5 Software design and implementation engineering process
    - §5.5.2 Design of software items
  - §5.6 Software validation process
    - §5.6.3 Validation activities with respect to the technical specification
    - §5.6.4 Validation activities with respect to the requirements baseline
  - §5.8 Software verification process
    - §5.8.3 Verification activities
  - §5.10 Software maintenance process
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - §5.11.2 Process implementation
    - §5.11.3 Software security analysis
    - §5.11.5 Security activities in the software life cycle
  - Annex U - Software code verification
- ECSS-Q-ST-80C
  - §5.6 Tools and supporting environment
    - §5.6.1 Methods and tools
    - §5.6.2 Development environment selection
  - §6.2 Requirements applicable to all software engineering processes
    - §6.2.3 Handling of critical software
    - §6.2.9 Software security
    - §6.2.10 Handling of security sensitive software
  - §6.3 Requirements applicable to individual software engineering processes or activities

- §7.2 Product quality requirements
  - §7.2.3 Test and validation documentation

Details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799).

149.3 GNAT Pro Development Environment

This section summarizes the main features of the two editions of AdaCore's GNAT Pro language toolsuite, *Enterprise* and *Assurance*. These editions correspond to different levels of customer requirements and are available for Ada, C, C++, and Rust.

Based on the GNU GCC technology, GNAT Pro for Ada supports the Ada 83, Ada 95, Ada 2005, and Ada 2012 standards, as well as selected features of Ada 2022. It includes:

- several Integrated Development Environments (See *Integrated Development Environments (IDEs)* (page 2773));
- a comprehensive toolsuite including a stack analysis tool (see *GNATstack* (page 2772)) and a visual debugger;
- a library that enables customers to develop their own source analysis tools for project-specific needs (see *Libadalang* (page 2771)); and
- other useful libraries and bindings.

For details on the tools and libraries supplied with GNAT Pro for Ada, see[702] and[703].

Other GNAT Pro products handle multiple versions of C (from C89 through C18), C++ (from C++98 through C++17), and Rust.

149.3.1 GNAT Pro Enterprise

GNAT Pro Enterprise is a development environment for producing critical software systems where reliability, efficiency, and maintainability are essential. Several features of GNAT Pro for Ada are noteworthy:

Run-Time Library Options

The product allows a variety of choices for the run-time library, based on the target platform. In addition to the Standard run-time, which is available for platforms that can support the full language capabilities, the product on some bare-metal or RTOS targets also includes restricted libraries that reduce the footprint and/or help simplify safety certification:

- The *Light Run-Time* library offers a minimal application footprint while retaining compatibility with the SPARK subset and verification tools. It supports a non-tasking Ada subset suitable for certification / qualification and/or storage-constrained embedded applications. It supersedes the ZFP (Zero FootPrint) and Cert run-time libraries from previous GNAT Pro releases.
- The *Light-Tasking Run-Time* library augments the Light run-time library with support for the Ravenscar and Jorvik tasking profiles. It supersedes the Ravenscar-Cert and Ravenscar-SFP libraries from previous GNAT Pro releases.
- The *Embedded Run-Time* library provides a subset of the Standard Ada run-time library suitable for target platforms lacking file I/O and networking support. It supersedes the Ravenscar-Full library from previous GNAT Pro releases.

[702] AdaCore. GNAT User's Guide for Native Platforms. URL: https://docs.adacore.com/live/wave/gnat_ugn/html/gnat_ugn/gnat_ugn.html.
[703] AdaCore. GNAT User's Guide Supplement for Cross Platforms. URL: https://docs.adacore.com/live/wave/gnat_ugx/html/gnat_ugx/gnat_ugx.html.

Although limited in terms of dynamic Ada semantics, these predefined libraries fully support static Ada constructs such as private types, generic templates, and child units. Some dynamic semantics are also supported. For example, tagged types (at library level) and other Object-Oriented Programming features are supported, as is dynamic dispatching. The general use of dynamic dispatching at the application level can be prevented through pragma `Restrictions`.

Details on these libraries may be found in the "Predefined GNAT Pro Run-Times" chapter ofPage 2769, 703.

Adapted versions of the earlier ZFP and Ravenscar-Cert libraries have been qualified under ECSS-E-ST-40C and ECSS-Q-ST-80C at criticality category B.

Run-Time Library Configurability

A traditional problem with predefined profiles is their inflexibility: if a feature outside a given profile is needed, then it is the developer's responsibility to address the certification issues deriving from its use. GNAT Pro for Ada accommodates this need by allowing the developer to define a profile for the specific set of features that are used. Typically this will be for features with run-time libraries that require associated certification materials. Thus the program will have a tailored run-time library supporting only those features that have been specified.

More generally, the configurable run-time capability allows specifying support for Ada's dynamic features in an à la carte fashion ranging from none at all to full Ada. The units included in the executable may be either a subset of the standard libraries provided with GNAT Pro, or specially tailored to the application. This latter capability is useful, for example, if one of the predefined profiles implements almost all the dynamic functionality needed in an existing system that has to meet new safety-critical requirements, and where the costs of adapting the application without the additional run-time support are considered prohibitive.

Enhanced Data Validity Checking

Improper or missing data validity checking is a notorious source of security vulnerabilities in software systems. Ada has always offered range checks for scalar subtypes, but GNAT Pro goes further, offering enhanced validity checking that can protect a program against malicious or accidental memory corruption, failed I/O devices, and so on. This feature is particularly useful in combination with automatic Fuzz testing, since it offers strong defense for invalid data at the software boundary of a system.

149.3.2 GNAT Pro Assurance

GNAT Pro Assurance extends GNAT Pro Enterprise with specialized support, including bug fixes and *known problems* analyses, on a specific version of the toolchain. This product edition is especially suitable for applications with long-lived maintenance cycles or assurance requirements, since critical updates to the compiler or other product components may become necessary years after the initial release.

Sustained Branches

Unique to GNAT Pro Assurance is a service known as a *sustained branch*: customized support and maintenance for a specific version of the product. A project on a sustained branch can monitor relevant known problems, analyze their impact and, if needed, update to a newer version of the product on the same development branch (i.e., not incorporating changes introduced in later versions of the product).

Sustained branches are a practical solution to the problem of ensuring toolchain stability while allowing flexibility in case an upgrade is needed to correct a critical problem.

Source to Object Traceability

Source-to-object traceability is required in standards such as DO - 178C/ED - 12C, and a GNAT Pro compiler option can limit the use of language constructs that generate object code that is not directly traceable to the source code. As an add-on service, AdaCore can perform an analysis that demonstrates this traceability and justifies any remaining cases of non-traceable code.

Compliance with the ECSS Standards

Supplementing the support provided by GNAT Pro for Ada (see *GNAT Pro and the ECSS Standards* (page 2775)), GNAT Pro Assurance helps compliance with the following requirements from ECSS-E-ST-40C and ECSS-Q-ST-80C:

- ECSS-E-ST-40C
  - §5.9 Software operation process
    - §5.9.2 Process implementation
    - §5.9.4 Software operation support
    - §5.9.5 User support
- ECSS-Q-ST-80C
  - §6.2 Requirements applicable to all software engineering processes
    - §6.2.6 Verification
  - §6.3 Requirements applicable to individual software engineering processes or activities
    - §6.3.9 Maintenance

149.3.3 Libadalang

Libadalang is a library included with GNAT Pro that gives applications access to the complete syntactic and semantic structure of an Ada compilation unit. This library is typically used by tools that need to perform some sort of static analysis on an Ada program.

AdaCore can assist customers in developing libadalang-based tools to meet their specific needs, as well as develop such tools upon request.

Typical libadalang applications include:

- Static analysis (property verification)
- Code instrumentation
- Design and document generation tools
- Metric testing or timing tools
- Dependency tree analysis tools
- Type dictionary generators
- Coding standard enforcement tools
- Language translators (e.g., to CORBA IDL)
- Quality assessment tools
- Source browsers and formatters
- Syntax directed editors

149.3.4 GNATstack

GNATstack is a static analysis tool included with GNAT Pro that enables an Ada/C software developer to accurately predict the maximum size of the memory stack required for program execution.

GNATstack statically predicts the maximum stack space required by each task in an application. The computed bounds can be used to ensure that sufficient space is reserved, thus guaranteeing safe execution with respect to stack usage. The tool uses a conservative analysis to deal with complexities such as subprogram recursion, while avoiding unnecessarily pessimistic estimates.

This static stack analysis tool exploits data generated by the compiler to compute worst-case stack requirements. It performs per-subprogram stack usage computation combined with control flow analysis.

GNATstack can analyze object-oriented applications, automatically determining maximum stack usage on code that uses dynamic dispatching in Ada. A dispatching call challenges static analysis because the identity of the subprogram being invoked is not known until run time. GNATstack solves this problem by statically determining the subset of potential targets (primitive operations) for every dispatching call. This significantly reduces the analysis effort and yields precise stack usage bounds on complex Ada code.

GNATstack's analysis is based on information known at compile time. When the tool indicates that the result is accurate, the computed bound can never be exceeded.

On the other hand, there may be cases in which the results will not be accurate (the tool will report such situations) because of some missing information (such as the maximum depth of subprogram recursion, indirect calls, etc.). The user can assist the tool by specifying missing call graph and stack usage information.

GNATstack's main output is the worst-case stack usage for every entry point, together with the paths that result in these stack sizes. The list of entry points can be automatically computed (all the tasks, including the environment task) or can be specified by the user (a list of entry points or all the subprograms matching a given regular expression).

GNATstack can also detect and display a list of potential problems when computing stack requirements:

- Indirect (including dispatching) calls. The tool will indicate the number of indirect calls made from any subprogram.
- External calls. The tool displays all the subprograms that are reachable from any entry point for which there is no stack or call graph information.
- Unbounded frames. The tool displays all the subprograms that are reachable from any entry point with an unbounded stack requirement. The required stack size depends on the arguments passed to the subprogram. For example:

```
procedure P(N : Integer) is
   S : String (1..N);
begin
   ...
end P;
```

- Cycles. The tool can detect all the cycles (i.e., potential recursion) in the call graph.

GNATstack allows the user to supply a text file with the missing information, such as the potential targets for indirect calls, the stack requirements for external calls, and the maximal size for unbounded frames.

Compliance with the ECSS Standards

The GNATstack tool can help meet several requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). In summary, these are the relevant sections of the two standards:

- ECSS-E-ST-40C
  - §5.8 Software verification process
    - §5.8.3 Verification activities
      - §5.8.3.5f Verification of code / source code robustness
  - Annex U - Software code verification
    - Verification check 12 (memory leaks)
- ECSS-Q-ST-80C
  - §5.6 Tools and supporting environment
    - §5.6.2 Development environment selection

149.3.5 GNAT Pro for Rust

The Rust language was designed for software that needs to meet stringent requirements for both assurance and performance: Rust is a memory-safe systems-programming language with software integrity guarantees (in both concurrent and sequential code) enforced by compile-time checks. The language is seeing growing use in domains such as automotive systems and is a viable choice for other high-assurance software.

AdaCore's GNAT Pro for Rust is a complete development environment for the Rust programming language, supporting both native builds and cross compilation to embedded targets. The product is not a fork of the Rust programming language or the Rust tools. Instead, GNAT Pro for Rust is a professionally supported build of a selected version of rustc and other core Rust development tools that offers stability for professional and high-integrity Rust projects. Critical fixes to GNAT Pro for Rust are upstreamed to the Rust community, and critical fixes made by the community to upstream Rust tools are backported as needed to the GNAT Pro for Rust code base. Additionally, the Assurance edition of GNAT Pro for Rust includes the *sustained branch* service (see *Sustained Branches* (page 2770)) that strikes the balance between tool stability and project flexibility.

149.3.6 Integrated Development Environments (IDEs)

GNAT Pro includes several graphical IDEs for invoking the build tools and accompanying utilities and monitoring their outputs.

GNAT Studio

GNAT Studio is a powerful and simple-to-use IDE that streamlines software development from the initial coding stage through testing, debugging, system integration, and maintenance. It is designed to allow programmers to get the most out of GNAT Pro technology.

Functionality

GNAT Studio's extensive navigation and analysis tools can generate a variety of useful information including call graphs, source dependencies, project organization, and complexity metrics, giving a thorough understanding of a program at multiple levels. The IDE allows interfacing with third-party version control systems, easing both development and maintenance.

Robustness, Flexibility and Extensibility

Especially suited for large, complex systems, GNAT Studio can import existing projects from other Ada implementations while adhering to their file naming conventions and retaining the existing directory organization. Through the multi-language capabilities of GNAT Studio, components written in C and C++ can also be handled. The IDE is highly extensible; additional tools can be plugged in through a simple scripting approach. It is also tailorable, allowing various aspects of the program's appearance to be customized in the editor.

Ease of Learning and Use

GNAT Studio is intuitive to new users thanks to its menu-driven interface with extensive online help (including documentation on all the menu selections) and *tool tips*. The Project Wizard makes it simple to get started, supplying default values for almost all of the project properties. For experienced users, it offers the necessary level of control for advanced purposes; e.g., the ability to run command scripts. Anything that can be done on the command line is achievable through the menu interface.

Support for Remote Programming

Integrated into GNAT Studio, Remote Programming provides a secure and efficient way for programmers to access any number of remote servers on a wide variety of platforms while taking advantage of the power and familiarity of their local PC workstations.

VS Code Extensions for Ada and SPARK

AdaCore's extensions to Visual Studio Code (VS Code) enable Ada and SPARK development with a lightweight editor, as an alternative to the full GNAT Studio IDE. Functionality includes:

- Syntax highlighting for Ada and SPARK files
- Code navigation
- Error diagnostics (errors reported in the Problems pane)
- Build integration (execution of GNAT-based toolchains from within VS Code)
- Display of SPARK proof results (green/red annotations from GNATprove)
- Basic IntelliSense (completion and hover information for known symbols)

Eclipse Support – GNATbench

GNATbench is an Ada development plug-in for Eclipse and Wind River's Workbench environment. The Workbench integration supports Ada development on a variety of VxWorks real-time operating systems. The Eclipse version is primarily for native applications, with some support for cross development. In both cases the Ada tools are tightly integrated.

GNATdashboard

GNATdashboard serves as a one-stop control panel for monitoring and improving the quality of Ada software. It integrates and aggregates the results of AdaCore's various static and dynamic analysis tools (GNATmetric, GNATcheck, GNATcoverage, SPARK Pro, among others) within a common interface, helping quality assurance managers and project leaders understand or reduce their software's technical debt, and eliminating the need for manual input.

GNATdashboard fits naturally into a continuous integration environment, providing users with metrics on code complexity, code coverage, conformance to coding standards, and more.

149.3.7 GNAT Pro and the ECSS Standards

GNAT Pro can help meet a number of requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). In summary, these are the relevant sections of the two standards:

- ECSS-E-ST-40C
  - §5.4 Software requirements and architecture engineering process
    - §5.4.3 Software architecture design
  - §5.5 Software design and implementation engineering process
    - §5.5.2 Design of software items
    - §5.5.3 Coding and testing
    - §5.5.4 Integration
  - §5.7 Software delivery and acceptance process
    - §5.7.3 Software acceptance
  - §5.8 Software verification process
    - §5.8.3 Verification activities
  - §5.9 Software operation process
    - §5.9.2 Process implementation
  - §5.10 Software maintenance process
    - §5.10.2 Process implementation
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - §5.11.2 Process implementation
    - §5.11.3 Software security analysis
    - §5.11.5 Security analysis in the software lifecycle
    - Annex U - Source code verification
      - Verification check 12 (memory leaks)
- ECSS-Q-ST-80C
  - §5.2 Software product assurance programme management
    - §5.2.7 Quality requirements and quality models
  - §5.6 Tools and supporting environments
    - §5.6.1 Methods and tools
    - §5.6.2 Development environment selection
  - §6.2 Requirements applicable to all software engineering processes
    - §6.2.3 Handling of critical software
    - §6.2.6 Verification
    - §6.2.9 Software security
  - §6.3 Requirements applicable to individual processes or activities
    - §6.3.4 Coding
    - §6.3.9 Maintenance

- §7.1 Product quality objectives and metrication
  - §7.1.3 Assurance objectives for product quality requirements
  - §7.1.5 Basic metrics

AdaCore's ZFP (Zero Footprint) minimal run-time library (superseded by the Light run-time in current GNAT Pro releases) on LEON2 ELF has been qualified at criticality category B, and the Ravenscar SFP (Small Footprint) QUAL run-time library (superseded by the Light-Tasking run-time) on LEON2 and LEON3 boards have been qualified at criticality category B (see[704]).

149.4 Static Verification: CodeSonar for Ada

CodeSonar for Ada is a set of Ada static analysis tools that complement GNAT Pro for Ada. These tools can save time and effort in general during software development and verification, and they are useful in particular in supporting compliance with ECSS standards.

149.4.1 Defects and Vulnerability Analyzer

One of the main tools in CodeSonar for Ada is an Ada source code analyzer that detects run-time and logic errors that can cause safety or security vulnerabilities in a codebase. This tool inspects the code for potential bugs before program execution, serving as an automated peer reviewer. It can be used on existing codebases, thereby helping vulnerability analysis during a security assessment or system modernization, and when performing impact analysis during updates. It can also be used on new projects, helping to find errors early in the development life-cycle when they are least costly to repair. Using control-flow, data-flow, and other advanced static analysis techniques, this analysis tool detects errors that would otherwise only be found through labor-intensive debugging.

The defects and vulnerability analyzer can be used from within the GNAT Pro development environment, or as part of a continuous integration regime. As a stand-alone tool, it can also be used with projects that do not use GNAT Pro for compilation.

CWE Compatibility

The tool can detect a number of "Dangerous Software Errors" in the MITRE Corporation's Common Weakness Enumeration, and the tool has been certified (under its previous name, CodePeer) by The MITRE Corporation as a "CWE-Compatible" productPage 2767, 700.

Here are the weaknesses that are detected:

[704] AdaCore. Press Release: European Space Agency Selects AdaCore's Qualified-Multitasking Solution for Spacecraft Software Development. September 24, 2019. URL: https://www.adacore.com/press/european-space-agency-selects-adacores-qualified-multitasking-solution-for-spacecraft-software-development.

Table 39: Defects and Vulnerability Analyzer and the CWE

CWE weakness	Description
CWE 120, 124, 125	Buffer overflow/underflow
CWE 136, 137	Variant record field violation, Use of incorrect type in inheritance hierarchy
CWE 190, 191	Numeric overflow/underflow
CWE 362, 366	Race condition
CWE 369	Division by zero
CWE 457	Use of uninitialized variable
CWE 476	Null pointer dereference
CWE 561	Dead (unreachable) code
CWE 563	Unused or redundant assignment
CWE 570	Expression is always false
CWE 571	Expression is always true
CWE 628	Incorrect arguments in call
CWE 667	Improper locking
CWE 682	Incorrect calculation
CWE 820	Missing synchronization
CWE 821	Incorrect synchronization
CWE 835	Infinite loop

Compliance with the ECSS Standards

The defects and vulnerability analyzer can help meet a number of requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). In summary, these are the relevant sections of the two standards:

- ECSS-E-ST-40C
  - §5.5 Software design and implementation engineering process
    - §5.5.2 Design of software items
  - §5.6 Software validation process
    - §5.6.3 Validation activities with respect to the technical specification
    - §5.6.4 Validation activities with respect to the requirements baseline
  - §5.8 Software verification process
    - §5.8.3 Verification activities
  - §5.10 Software maintenance process
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - §5.11.2 Process implementation
    - §5.11.3 Software security analysis
    - §5.11.5 Software analysis in the software life cycle
  - Annex U - Software code verification
- ECSS-Q-ST-80C
  - §5.6. Tools and supporting environment
    - §5.6.1 Methods and tools
    - §5.6.2 Development environment selection

  - §6.2 Requirements applicable to all software engineering processes
    * §6.2.3 Handling of critical software
    * §6.2.6 Verification
    * §6.2.9 Software security
  - §7.1 Product quality objectives and metrication
    * §7.1.3 Assurance activities for product quality requirements

149.4.2 GNATmetric

GNATmetric is a static analysis tool that calculates a set of commonly used industry metrics, thus allowing developers to estimate code complexity and better understand the structure of the source program. This information also facilitates satisfying the requirements of certain software development frameworks and is useful in conjunction with GNATcheck (for example, in reporting and limiting the maximum subprogram nesting depth).

Compliance with the ECSS Standards

The GNATmetric tool can help meet a number of requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). Here is a summary:

- ECSS-E-ST-40C
  - §5.10 Software maintenance process
    * §5.10.4 Modification implementation
- ECSS-Q-ST-80C
  - §5.2 Software product assurance programme management
    * §5.2.7 Quality requirements and quality models
  - §6.3 Requirements applicable to individual software engineering processes or activities
    * §6.3.4 Coding
  - §7.1 Product quality objectives and metrication
    * §7.1.3 Assurance activities for product quality requirements
    * §7.1.5 Basic metrics

149.4.3 GNATcheck

GNATcheck is a coding standard verification tool that is extensible and rule-based. It allows developers to completely define a project-specific coding standard as a set of rules, for example a subset of permitted language features and/or code formatting and style conventions. It verifies a program's conformance with the resulting rules and thereby facilitates demonstration of a system's compliance with a certification standard's requirements on language subsetting.

GNATcheck provides:

- An integrated "Ada Restrictions" mechanism for banning specific features from an application. This can be used to restrict features such as tasking, exceptions, dynamic allocation, fixed- or floating point, input/output, and unchecked conversions.
- Restrictions specific to GNAT Pro, such as banning features that result in the generation of implicit loops or conditionals in the object code, or in the generation of elaboration code.

- Additional Ada semantic rules resulting from customer input, such as ordering of parameters, normalized naming of entities, and subprograms with multiple returns.
- An easy-to-use interface for creating and using a complete coding standard.
- Generation of project-wide reports, including evidence of the level of compliance with a given coding standard.
- Over 30 compile-time warnings from GNAT Pro that detect typical error situations, such as local variables being used before being initialized, incorrect assumptions about array lower bounds, certain cases of infinite recursion, incorrect data alignment, and accidental hiding of names.
- Style checks that allow developers to control indentation, casing, comment style, and nesting level.

AdaCore's GNATformat tool[705], which formats Ada source code according to the GNAT coding style[706], can help avoid having code that violates GNATcheck rules. GNATformat is included in the GNAT Pro for Ada toolchain.

GNATcheck comes with a query language (LKQL, for Language Kit Query Language) that lets developers define their own checks for any in-house rules that need to be followed. GNATcheck can thus be customized to meet an organization's specific requirements, processes and procedures.

Compliance with the ECSS Standards

The GNATcheck tool can help meet a number of requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). In summary, these are the relevant sections of the two standards:

- ECSS-E-ST-40C
  - §5.8 Software verification process
    - §5.8.3 Verification activities
      - §5.8.3.4 Verification of the software detailed design
  - §5.10 Software maintenance process
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - §5.11.2 Process implementation
    - §5.11.3 Software security analysis
    - §5.11.5 Software analysis in the software life cycle
  - Annex U - Software code verification
    - Verification check 3 (infinite loops)
    - Verification check 4 (misuse of arithmetic and logical operators)
- ECSS-Q-ST-80C
  - §5.6 Tools and supporting environment
    - §5.6.2 Development environment selection
  - §6.2 Requirements applicable to all software engineering processes

    - §6.3.4 Coding
  - §7.1 Product quality objectives and metrication
    - §7.1.3 Assurance activities for product quality requirements

149.5 GNAT Dynamic Analysis Suite (GNAT DAS)

149.5.1 GNATtest

The GNATtest tool helps create and maintain a complete unit testing infrastructure for complex projects. It captures the simple idea that each public subprogram (these are known as *visible* subprograms in Ada) should have at least one corresponding unit test. GNATtest takes a project file as input, and produces two outputs:

- The complete harnessing code for executing all the unit tests under consideration. This code is generated completely automatically.
- A set of separate test stubs for each subprogram to be tested. These test stubs are to be completed by the user.

GNATtest handles Ada's Object-Oriented Programming features and can be used to help verify tagged type substitutability (the Liskov Substitution Principle) that can be used to demonstrate consistency of class hierarchies.

Testing a private subprogram is outside the scope of GNATtest but can be implemented by defining the relevant testing code in a private child of the package that declares the private subprogram. Additionally, hybrid verification can help (see *Hybrid Verification* (page 2762)): augmenting testing with the use of SPARK to formally prove relevant properties of the private subprogram.

149.5.2 GNATemulator

GNATemulator is an efficient and flexible tool that provides integrated, lightweight target emulation.

Based on the QEMU technology, a generic and open-source machine emulator and virtualizer, GNATemulator allows software developers to compile code directly for their target architecture and run it on their host platform, through an approach that translates from the target object code to native instructions on the host. This avoids the inconvenience and cost of managing an actual board, while offering an efficient testing environment compatible with the final hardware.

There are two basic types of emulators. The first can serve as a surrogate for the final hardware during development for a wide range of verification activities, particularly those that require time accuracy. However, they tend to be extremely costly, and are often very slow. The second, which includes GNATemulator, does not attempt to be a complete time-accurate target board simulator, and thus it cannot be used for all aspects of testing. But it does provide a very efficient and cost-effective way to execute the target code very early in the development and verification processes. GNATemulator thus offers a practical compromise between a native environment that lacks target emulation capability, and a cross configuration where the final target hardware might not be available soon enough or in sufficient quantity.

149.5.3 GNATcoverage

GNATcoverage is a code coverage analysis tool. Its results are computed from trace files that show which program constructs have been exercised by a given test campaign. With source code instrumentation, the tool produces these files by executing an alternative version of the program, built from source code instrumented to populate coverage-related data structures. Through an option to GNATcoverage, the user can specify the granularity of the analysis: statement coverage, decision coverage, or Modified Condition / Decision Coverage (MC/DC).

Source-based instrumentation brings several major benefits: efficiency of tool execution (much faster than alternative coverage strategies using binary traces and target emulation, especially on native platforms), compact-size source trace files independent of execution duration, and support for coverage of shared libraries.

149.5.4 GNATfuzz

GNATfuzz is a fuzzing tool; i.e., a tool that automatically and repeatedly executes tests and generates new test cases at a very high frequency to detect faulty behavior of the system under test. Such anomalous behavior is captured by monitoring the system for triggered exceptions, failing built-in assertions, and signals such as SIGSEGV.

Fuzz testing has proven to be an effective mechanism for finding corner-case vulnerabilities that traditional human-driven verification mechanisms, such as unit and integration testing, can miss. Since such vulnerabilities can often lead to malicious exploitations, fuzzing technology can help meet security verification requirements.

However, fuzz-testing campaigns are complex and time-consuming to construct, execute and monitor. GNATfuzz simplifies the process by analyzing a code base and identifying subprograms that can act as fuzz-test entry points. GNATfuzz then automates the creation of test harnesses suitable for fuzzing. In addition, GNATfuzz will automate the building, executing and analyzing of fuzz-testing campaigns.

GNATfuzz can serve a useful role as part of the software development and verification life cycle processes. For example, by detecting anomalous behavior such as data corruption due to task or interrupt conflicts, GNATfuzz can help prevent defects from being introduced into the source code.

149.5.5 TGen

TGen is an experimental run-time library / marshalling technology that can be used by *GNATtest* (page 2780) and/or *GNATfuzz* (page 2781) to automate the production of test cases for Ada code. It performs type-specific low-level processing to generate test vectors for subprogram parameters, such as uniform value distribution for scalar types and analogous strategies for unconstrained arrays and record discriminants. A command-line argument specifies the number of test values to be generated, and these can then be used as input to test cases created by GNATtest.

TGen can also be used with GNATfuzz, to help start a fuzz-testing campaign when the user supplies an initial set of test cases where some may contain invalid data. GNATfuzz will utilize coverage-driven fuzzer mutations coupled with TGen to convert invalid test cases into valid ones. TGen represents test data values compactly, removing a large amount of memory padding that would otherwise be present for alignment of data components. With its space-efficient representation, TGen significantly increases the probability of a successful mutation that results in a new valid test case.

149.5.6 GNAT Dynamic Analysis Suite and the ECSS Standards

The GNAT Dynamic Analysis Suite can help meet a number of requirements in ECSS-E-ST-40C and ECSS-Q-ST-80C; details are provided in chapters *Compliance with ECSS-E-ST-40C* (page 2785) and *Compliance with ECSS-Q-ST-80C* (page 2799). In summary, these are the relevant sections of the two standards:

- ECSS-E-ST-40C
  - §5.5 Software design and implementation engineering process
    - §5.5.3 Coding and testing
    - §5.5.4 Integration
  - §5.6 Software validation process
    - §5.6.3 Validation activities with respect to the technical specification
    - §5.6.4 Validation activities with respect to the requirements baseline
  - §5.8 Software verification process
    - §5.8.3 Verification activities
  - §5.10 Software maintenance process
    - §5.10.4 Modification implementation
  - §5.11 Software security process
    - §5.11.2 Process implementation
    - §5.11.3 Software security analysis
    - §5.11.5 Security analysis in the software lifecycle
- ECSS-Q-ST-80C
  - §5.6 Tools and supporting environment
    - §5.6.1 Methods and tools
    - §5.6.2 Development environment selection
  - §6.2 Requirements applicable to all software engineering processes
    - §6.2.3 Handling of critical software
    - §6.2.9 Software security
  - §6.3 Requirements applicable to individual software engineering processes or activities
    - §6.3.5 Testing and validation
  - §7.1 Product quality objectives and metrication
    - §7.1.3 Assurance activities for product quality requirements
    - §7.1.5 Basic metrics
  - §7.2 Product quality requirements
    - §7.2.3 Test and validation documents

149.6 Support and Expertise

Every AdaCore product subscription comes with front-line support provided directly by the product developers themselves, who have deep expertise in the Ada language, domain-specific software certification / qualification standards, compilation technologies, embedded system technology, and static and dynamic verification. AdaCore's development en-

gineers have extensive experience supporting customers in critical areas including space, commercial and military avionics, air traffic management/control, railway, and automotive. Customers' questions (requests for guidance on feature usage, suggestions for technology enhancements, or defect reports) are handled efficiently and effectively.

Beyond this bundled support, AdaCore also provides Ada language and tool training, on-site consulting on topics such as how to best deploy the technology, and mentoring assistance on start-up issues. On-demand tool development or ports to new platforms are also available.

COMPLIANCE WITH ECSS-E-ST-40C

The ECSS-E-ST-40C standard is concerned with software engineering — the principles and techniques underlying the production of code that is reliable, safe, secure, readable, maintainable, portable and efficient. These are the goals that drove the design of the Ada language (and its SPARK subset), whose features assist in designing a modular and robust system architecture and in preventing or detecting errors such as type mismatches or buffer overruns that can arise in other languages.

This chapter explains how Ada and SPARK, together with the relevant AdaCore development and verification tools, can help a space software supplier meet many of the requirements presented in ECSS-E-ST-40C. The section numbers in braces refer to the associated content in ECSS-E-ST-40C.

150.1 Software requirements and architecture engineering process {§5.4}

150.1.1 Software architecture design {§5.4.3}

Transformation of software requirements into a software architecture {§5.4.3.1}

- "The supplier shall transform the requirements for the software into an architecture that describes the top-level structure; identifies the software components, ensuring that all the requirements for the software item are allocated to the software components and later refined to facilitate detailed design; covers as a minimum hierarchy, dependency, interfaces and operational usage for the software components; documents the process, data and control aspects of the product; describes the architecture static decomposition into software elements such as packages, classes or units; describes the dynamic architecture, which involves the identification of active objects such as threads, tasks and processes; describes the software behavior." {§5.4.3.1a}
  - The Ada and SPARK languages (and thus the GNAT Pro Ada and SPARK Pro toolsuites) directly support this requirement. Relevant features include packages, child libraries, subunits, private types, tasking, and object-oriented programming (tagged types). The GNATstub utility (included with GNAT Pro Ada) is useful here; it generates empty package bodies (*stubs*) from a software design's top-level API (package specs).

Software design method {§5.4.3.2}

- "The supplier shall use a method (e.g., object oriented or functional) to produce the static and dynamic architecture including: software elements, their interfaces and; software elements relationships." {§5.4.3.2a}
  - Ada and SPARK are methodology agnostic and fully support both object-oriented and functional styles.

Selection of a computational model for real-time software {§5.4.3.3}

- "The dynamic architecture design shall be described according to an analytical computational model." {§5.4.3.3a}
  - The Ada and SPARK tasking facility supports a stylistic idiom that is amenable to Rate Monotonic Analysis, allowing static verification that real-time deadlines will be met.

Description of software behavior {§5.4.3.4}

- "The software design shall also describe the behaviour of the software, by means of description techniques using automata and scenarios." {§5.4.3.4a}
  - Ada and SPARK are appropriate target languages for tools that support such techniques.

Development and documentation of the software interfaces {§5.4.3.5}

- "The supplier shall develop and document a software preliminary design for the interfaces external to the software item and between the software components of the software item." {§5.4.3.5a}
  - The supplier can use the Ada / SPARK package facility to specify the interfaces, both external and internal. The contract-based programming features provide additional expressive power, allowing the specification of pre- and postconditions for the subprograms comprising an interface.

Definition of methods and tools for software intended for reuse {§5.4.3.6}

- "The supplier shall define procedures, methods and tools for reuse, and apply these to the software engineering processes to comply with the reusability requirements for the software development." {§5.4.3.6a}
  - Ada and SPARK facilitate reuse via the separate compilation semantics (which allows *bottom-up* development by reusing existing libraries) and the generic facility (which, for example, allows a module to be defined in a general and type-independent fashion and then instantiated with specific types as needed). The semantics for these features enforces safe reuse:
    - All checks that are performed within a single compilation unit are also enforced across separate compilation boundaries.
    - A post-compilation pre-link check detects and prevents *version skew* (building an executable where some compilation unit depends on an obsolescent version of another unit).
    - Unlike the situation with C++ templates, a type mismatch in an Ada generic instantiation is detected and prevented at compile time, ensuring consistency between the instantiation and the generic unit.

150.2 Software design and implementation engineering process {§5.5}

150.2.1 Design of software items {§5.5.2}

Detailed design of each software component {§5.5.2.1}

- "The supplier shall develop a detailed design for each component of the software and document it." {§5.5.2.1a}

  - Ada / SPARK features, including packages and child units, and thus GNAT Pro for Ada and SPARK Pro, help meet this requirement. The contract-based programming feature (e.g., pre- and postconditions) allows the supplier to express low-level requirements as part of the software architecture, facilitating the low-level design of algorithms.

- "Each software component shall be refined into lower levels containing software units that can be coded, compiled, and tested." {§5.5.2.1b}
  - Relevant Ada / SPARK features include packages, child units, and subunits.

Development and documentation of the software interfaces detailed design {§5.5.2.2}

- "The supplier shall develop and document a detailed design for the interfaces external to the software items, between the software components, and between the software units, in order to allow coding without requiring further information." {§5.5.2.2a}
  - Ada / SPARK features, including packages and child units, and thus SPARK Pro and GNAT Pro for Ada, help meet this requirement. The contract-based programming feature (e.g., pre- and postconditions) allows the supplier to express low-level requirements as part of the interfaces, facilitating the implementation of algorithms.

Production of the detailed design model {§5.5.2.3}

- "The supplier shall produce the detailed design model of the software components defined during the software architectural design, including their static, dynamic and behavioural aspects." {§5.5.2.3a}
  - Ada / SPARK features such as packages, child units, and contract-based programming, and thus SPARK Pro and GNAT Pro for Ada, help meet this requirement.

Software detail design method {§5.5.2.4}

- "The supplier shall use a design method (e.g. object oriented or functional method) to produce the detailed design including: software units, their interfaces, and; (*sic*) software units relationships." {§5.5.2.4a}
  - Ada and SPARK are methodology agnostic and fully support both object-oriented and functional styles.

Detailed design of real-time software {§5.5.2.5}

- "The dynamic design model shall be compatible with the computational model selected during the software architectural design model" {§5.5.2.5a}
  - The Ada / SPARK tasking model allows a straightforward mapping from the architectural design (where the system comprises a collection of tasks that interact via protected shared resources) to the detailed design.
- "The supplier shall document and justify all timing and synchronization mechanisms" {§5.5.2.5b}
  - The Ada / SPARK tasking model supplies the necessary timing and synchronization support.
- "The supplier shall document and justify all the design mutual exclusion mechanisms to manage access to the shared resources." {§5.5.2.5c}
  - The Ada / SPARK tasking model supplies the necessary mutual exclusion mechanisms (protected types/objects, pragma Atomic). The protected type/object facility prevents certain kinds of race conditions: in state-based mutual exclusion, the

state of an object cannot change between the time that a task evaluates the state condition and when it executes the code based on that state. Other race conditions can be detected by the Defects and Vulnerability Analyzer in CodeSonar for Ada.

- "The supplier shall document and justify the use of dynamic allocation of resources." {§5.5.2.5d}
  - Ada has a general and flexible mechanism for dynamic memory management, including the ability of the programmer to specify the semantics of allocation and deallocation within a storage pool. This can be used, for example, to define a fragmentation-free strategy for memory management with constant time for allocation and deallocation. The latest version of SPARK includes a facility for safe pointers.
- "The supplier shall ensure protection against problems that can be induced by the use of dynamic allocation of resources, e.g. memory leaks." {§5.5.2.5e}
  - Ada includes a variety of mechanisms that assist in preventing dynamic memory management issues. The `No_Standard_Allocators_After_Elaboration` argument to pragma `Restrictions` produces a run-time check that detects attempts to perform allocations from a standard storage pool after elaboration (initialization). Depending on the program structure, static analysis by the Defects and Vulnerability Analyzer in CodeSonar for Ada may be able to determine that this check will never fail.

Utilization of description techniques for the software behaviour {§5.5.2.6}

- "The behavioural design of the software units shall be described by means of techniques using automata and scenarios." {§5.5.2.6a}
  - Ada and SPARK are appropriate target languages for tools that support such techniques.

150.2.2 Coding and testing {§5.5.3}

Development and documentation of the software units {§5.5.3.1}

- "The supplier shall develop and document the following: the coding of each software unit; the build procedures to compile and link software units" {§5.5.3.1a}
  - The GNAT Pro project and gprbuild facility automate the build process and prevent *version skew*.

Software unit testing {§5.5.3.2}

- "The supplier shall develop and document the test procedures and data for testing each software unit" {§5.5.3.2a}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.
- "The supplier shall test each software unit ensuring that it satisfies its requirements and document the test results." {§5.5.3.2b}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.
- "The unit test shall exercise: code using boundaries at *n-1*, *n*, *n+1* including looping instructions *while*, *for* and tests that use comparisons; all the messages and error cases defined in the design document; the access of all global variables as specified in the design document; out of range values for input data, including values that can

cause erroneous results in mathematical functions; the software at the limits of its requirements (stress testing)." {§5.5.3.2c}

  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.

150.2.3 Integration {§5.5.4}

Software units and software component integration and testing {§5.5.4.2}

- "The supplier shall integrate the software units and software components, and test them, as the aggregates are developed, in accordance with the integration plan, ensuring each aggregate satisfies the requirements of the software item and that the software item is integrated at the conclusion of the integration activity." {§5.5.4.2a}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process, supplementing the GNAT Pro for Ada compilation facilities.

150.2.4 Validation activities with respect to the technical specification {§5.6.3}

Development and documentation of a software validation specification with respect to the technical specification {§5.6.3.1}

- "The supplier shall develop and document, for each requirement of the software item in TS [Technical Specification] (including ICD [Interface Control Document]), a set of tests, test cases (inputs, outputs, test criteria) and test procedures ...." {§5.6.3.1a}
  - AdaCore's GNAT Pro Ada environment and GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can support this process.
- "Validation shall be performed by test." {§5.6.3.1b}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.
- "If it can be justified that validation by test cannot be performed, validation shall be performed by either analysis, inspection or review of design" {§5.6.3.1c}
  - The Defects and Vulnerability Analyzer (see *Defects and Vulnerability Analyzer* (page 2776)) in CodeSonar for Ada and/or SPARK Pro may be able to show that a run-time check will always succeed and that no test case will trigger a failure.

150.2.5 Validation activities with respect to the requirements baseline {§5.6.4}

Development and documentation of a software validation specification with respect to the requirements baseline {§5.6.4.1}

- "The supplier shall develop and document, for each requirement of the software item in RB [Requirements Baseline] (including IRD [Interface Requirements Document]), a set of tests, test cases (inputs, outputs, test criteria) and test procedures ...." {§5.6.4.1a}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.
- "Validation shall be performed by test." {§5.6.4.1b}
  - AdaCore's GNAT Dynamic Analysis Suite (see *GNAT Dynamic Analysis Suite (GNAT DAS)* (page 2780)) can assist in this process.

- "If it can be justified that validation by test cannot be performed, validation shall be performed by either analysis, inspection or review of design" {§5.6.4.1c}
  - The Defects and Vulnerability Analyzer (see *Defects and Vulnerability Analyzer* (page 2776)) in CodeSonar for Ada and/or SPARK Pro may be able to show that a run-time check will always succeed and that no test case will trigger a failure.

150.3 Software delivery and acceptance process {§5.7}

150.3.1 Software acceptance {§5.7.3}

Executable code generation and installation {§5.7.3.3}

- "The acceptance shall include generation of the executable code from configuration managed source code components and its installation on the target environment." {§5.7.3.3a}
  - The GNAT Pro project and gprbuild facility can assist in the build and installation process.

150.4 Software verification process {§5.8}

150.4.1 Verification activities {§5.8.3}

Verification of the software detailed design {§5.8.3.4}

- "The supplier shall verify the software detailed design ensuring that: ... 5. testing is feasible, by assessing that: (a) controllability and observability features are identified and included in the detailed design in order to prepare the effective testing of the performance requirements; (b) computationally invariant properties and temporal properties are added within the design; (c) fault injection is possible. ... 7. the design is correct with respect to requirements and interfaces, including safety, security, and other critical requirements; 8. the design implements proper sequence of events, inputs, outputs, interfaces, logic flow, allocation of timing and sizing budgets, and error handling; ..." {§5.8.3.4a}
  - SPARK (and GNATprove) help meet criteria 5, 7, and 8.

Verification of code {§5.8.3.5}

- "The supplier shall verify the software code ensuring at least that: 1. the code is externally consistent with the requirements and design of the software item; 2. there is internal consistency between software units; 3. the code is traceable to design and requirements, testable, correct, and in conformity to software requirements and coding standards; 4. the code that is not traced to the units is justified; 5. the code implements proper events sequences, consistent interfaces, correct data and control flow, completeness, appropriate allocation of timing and sizing budgets; 6. the code implements safety, security, and other critical requirements correctly as shown by appropriate methods; 7. the code is implemented in a way that it cannot result in runtime errors; 8. the effects of any residual runtime errors are controlled through error handling." {§5.8.3.5a}
  - SPARK (and GNATprove) help meet criterion 1.
  - Ada's strong typing and interface checks (and thus GNAT Pro for Ada) help meet criterion 2.
  - For criterion 3, the Defects and Vulnerability Analyzer (see *Defects and Vulnerability Analyzer* (page 2776)) in CodeSonar for Ada and/or SPARK Pro can help

verify correctness, and the GNATcheck utility included in CodeSonar for Ada (see *GNATcheck* (page 2778)) can enforce conformance with a coding standard.

- For criterion 5, Ada's strong typing and interface checks, as well as SPARK and GNATprove, can help show consistent interfaces and correct data flow.
- The Defects and Vulnerability Analyzer (see *Defects and Vulnerability Analyzer* (page 2776)) in CodeSonar for Ada, SPARK Pro, and the standard semantic checks performed by the GNAT Pro compiler can help meet criterion 6.
- CodeSonar for Ada and SPARK / GNATprove can statically detect potential run-time errors and thereby help meet criterion 7.
- Ada's exception handling facility can help meet criterion 8.

- "The supplier shall verify that the following code coverage is achieved:

Code coverage versus criticality category	A	B	C	D
Source code statement coverage	100.00%	100.00%	TBA	TBA
Source code decision coverage	100.00%	100.00%	TBA	TBA
Source code modified condition and decision coverage	100.00%	TBA	TBA	TBA

Note: 'TBA' means that the value is to be agreed with the customer and measured as per ECSS-Q-ST-80C clause 6.3.5.2." {§5.8.3.5b}

- The GNATcoverage tool (see *GNATcoverage* (page 2781)) in the GNAT Dynamic Analysis Suite can help meet this requirement.

- "The supplier shall measure code coverage by analysis of the results of the execution of tests." {§5.8.3.5c}
  - The GNATcoverage tool (see *GNATcoverage* (page 2781)) in the GNAT Dynamic Analysis Suite can help meet this requirement.
- "If it can be justified that the required percentage cannot be achieved by test execution, then analysis, inspection or review of design shall be applied to the non-covered code." {§5.8.3.5d}
  - The GNATcoverage tool (see *GNATcoverage* (page 2781)) in the GNAT Dynamic Analysis Suite can help meet this requirement.
- "In case the traceability between source code and object code cannot be verified, the supplier shall perform additional code coverage analysis on object code level as follows:

Code coverage versus criticality category	A	B	C	D
Object code coverage	100.00%	N/A	N/A	N/A

Note: 'N/A' means not applicable.

Note: The use of some compiler optimization options can make the traceability between source code and object code not possible." {§5.8.3.5e}

- The GNATcoverage tool (see *GNATcoverage* (page 2781)) in the GNAT Dynamic Analysis Suite can help meet this requirement.
- AdaCore can prepare an analysis of traceability between source and object code; the company has provided this to customers in connection with certification under the DO-178C/ED-12C standard for airborne software for the commercial aviation industry.

- "The supplier shall verify source code robustness. AIM: use static analysis for the errors that are difficult to detect at run-time." {§5.8.3.5f}
  - Errors such as division by zero, null pointer dereferencing, array indices out of bounds, and many others are flagged at run-time by raising an exception. Effective practice is to keep these checks enabled during development and then, after verifying either statically or through sufficient testing that the run-time checks are not needed, disable the checks in the final code for maximal efficiency.
  - The Defects and Vulnerability Analyzer (see *Defects and Vulnerability Analyzer* (page 2776)) in CodeSonar for Ada will detect such errors as well as many others, including suspicious constructs that, although legitimate Ada, are likely logic errors.
  - SPARK Pro will enforce the SPARK subset and can be used to demonstrate absence of run-time errors.
  - The GNATstack tool in GNAT Pro computes the potential maximum stack usage for each task in a program. Combining the result with a separate analysis showing the maximal depth of recursion, the developer can allocate sufficient stack space for program execution and prevent stack overflow.

Schedulability analysis for real-time software {§5.8.3.11}

- "As part of the verification of the software requirements and architectural design, the supplier shall use an analytical model to perform a schedulability analysis and prove that the design is feasible." {§5.8.3.11a}
  - The Ada Ravenscar profile restricts the tasking model to enable precise schedulability analysis, including Rate-Monotonic Analysis (RMA).

150.5 Software operation process {§5.9}

150.5.1 Process implementation {§5.9.2}

Problem handling procedures definition {§5.9.2.3}

- "The SOS [Software Operation Support] entity shall establish procedures for receiving, recording, resolving, tracking problems, and providing feedback." {§5.9.2.3a}
  - In the event that a product problem is due to a defect in an AdaCore tool (e.g., a code generation bug), AdaCore has a rigorous QA process for responding to and resolving such issues. The *sustained branch* service, which is included with a GNAT Pro Assurance subscription, helps by ensuring that a specific version of the toolchain is maintained over the lifetime of the supplier's project.
- "The SOS entity shall ensure that information regarding problems that can have an impact on security is protected." {§5.9.2.3b}
  - AdaCore's internal processes for maintaining sensitive data help to meet this criterion.

150.5.2 Software operation support {§5.9.4}

Problem handling {§5.9.4.2}

- "Encountered problems shall be recorded and handled in accordance with the applicable procedures." {§5.9.4.2a}

  - As described above in connection with clause 5.9.2.3, AdaCore's QA process, and more specifically the GNAT Pro Assurance sustained branch service with its management of Known Problems, can help meet this requirement when an issue arises that is due to an AdaCore tool.

Vulnerabilities in operations {§5.9.4.3}

- "During operations, security vulnerabilities, threats and exploits shall be: 1. continuously monitored; 2. subject to further security analysis when evaluated relevant to the security of the system; 3. maintained for auditing purposes even when evaluated not relevant to the security of the system." {§5.9.4.3a}
  - The ability to express security-related requirements as contracts in the Ada source code, with run-time checks when needed, helps to meet criterion 1.

150.5.3 User support §5.9.5

Provisions of work-around solutions {§5.9.5.3}

- "If a reported problem has a temporary work-around solution before a permanent solution can be released, the SOS entity shall give to the originator of the problem report the option to use it." {§5.9.5.3a}
  - As part of the GNAT Pro Assurance sustained branch service, AdaCore can supply work-arounds to critical problems prior to releasing a permanent solution.

150.6 Software maintenance process {§5.10}

150.6.1 Process implementation {§5.10.2}

Long term maintenance for flight software {§5.10.2.2}

- "The maintainer shall propose solutions to be able to implement and upload modifications to the spacecraft up to its end of life." {§5.10.2.2a}
  - AdaCore's *sustained branch* service, which is included with a GNAT Pro Assurance subscription, in effect means that the compilation environment will receive support and not become obsolescent.

150.6.2 Modification implementation {§5.10.4}

Invoking of software engineering processes for modification implementation {§5.10.4.3}

- "The maintainer shall apply the software engineering processes specified in clauses 5.3 to 5.8 and 5.11 that are relevant to the scope of the modifications, using the tailoring applied during the development of the software." {§5.10.4.3a}
  - The Ada and SPARK languages have specific features that support the design of modular, maintainable software with high cohesion and low coupling. These include encapsulation (private types, separation of specification from implementation), hierarchical child libraries, and object-oriented programming (tagged types). By exploiting these features and utilizing GNAT Pro for Ada and SPARK Pro, the developer can localize the impact of maintenance changes.
  - CodeSonar for Ada and the GNAT Dynamic Analysis Suite can ensure that any modifications meet the verification criteria applicable to the original software.

150.7 Software security process {§ 5.11}

150.7.1 Process implementation {§ 5.11.2}

- "A software security management plan shall be produced documenting: ... 7. the tools, methods and procedures to be used...." {§ 5.11.2a}
  - The Ada and SPARK languages, GNAT Pro for Ada, CodeSonar for Ada, the GNAT Dynamic Analysis Suite, and the SPARK Pro toolset support the software security management plan.

150.7.2 Software security analysis {§ 5.11.3}

- "The methods to be used for the security analysis shall be identified as part of the planning of the project." {§ 5.11.3b}
  - The Ada and SPARK languages, GNAT Pro for Ada, CodeSonar for Ada, the GNAT Dynamic Analysis Suite, and the SPARK Pro toolset help meet this requirement. For example:
    - Ada's compile-time checks prevent unsafe practices such as treating an integer value as a pointer.
    - The Defects and Vulnerability Analyzer in CodeSonar for Ada can detect a number of dangerous software errors in the MITRE Corporation's Common Weakness Enumeration.
    - The SPARK language and SPARK Pro can enforce security-related properties such as correct information flows and absence of run-time errors.
    - GNATfuzz can be used to stress test the software with malformed input values.

150.7.3 Security activities in the software life cycle {§ 5.11.5}

Security in the requirements baseline {§ 5.11.5.1}

- "The security assurance requirements shall determine the type and extent of security verification and validation activities, including testing, to be conducted.... Security verification and validation activities can include, for example, fuzzing tests...." {§ 5.11.5.1c}
  - The Ada and SPARK languages, GNAT Pro for Ada, CodeSonar for Ada, the GNAT Dynamic Analysis Suite, and the SPARK Pro toolset help meet this requirement.

Security in the detailed design and implementation engineering {§ 5.11.5.3}

- "The software security analysis shall be used during verification and validation activities to evaluate iteratively residual vulnerabilities and to reassess security risks." {§ 5.11.5.3b}
  - The Ada and SPARK languages, CodeSonar for Ada, the GNAT Dynamic Analysis Suite, and the SPARK Pro toolset help meet this requirement. For examples, see *Software security analysis {§ 5.11.3}* (page 2794).

150.8 Software code verification {Annex U (informative)}

- "The following checks are expected to be performed on the software code:

1. the code implements numerical protection mechanisms (e.g. against overflow and underflow, division by zero);
2. the code does not perform out of bounds accesses - e.g. underrun or overrun of buffers, arrays or strings;
3. the code does not include any infinite loop other than the main loop of the software and the main loops of cyclic tasks;
4. the code appropriately uses arithmetical and logical operators (e.g. arithmetical OR vs. logical OR);
5. implicit type conversions do not lead to arithmetical errors;
6. the lifetime of variables is consistent with their use;
7. the code makes proper use of static/global functions/variables to enforce the correct level of visibility;
8. the code makes proper use of volatile variables for all variables that can be modified asynchronously (e.g. hardware access, memory-mapped I/O);
9. the code does not perform invalid memory accesses (e.g. NULL dereferences);
10. the code does not access uninitialized variables;
11. the code does not perform unused assignments, unless this is done to trigger HW side-effects;
12. there are no memory leaks;
13. pointer arithmetic is justified and types of operands are consistent;
14. the code does not lead to race conditions." {§ U.2}

Table 40 shows how AdaCore's technologies help meet these requirements:

Table 40: Verification Support

Verification check #	Technology	Explanation
1	Ada language, GNAT Pro for Ada, GNAT Pro Assurance	Run-time check[707]
	SPARK language, SPARK Pro	Static check
	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
2	Ada language, GNAT Pro for Ada, GNAT Pro Assurance	Run-time check[707]
	SPARK language, SPARK Pro	Static check
	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
3	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
	GNATcheck (in CodeSonar for Ada)	User-defined rule
	SPARK language, SPARK Pro	Static check
4	Ada language, GNAT Pro for Ada, GNAT Pro Assurance SPARK language, SPARK Pro	Static check
	GNATcheck (in CodeSonar for Ada)	User-defined rule
5	Ada language, GNAT Pro for Ada, GNAT Pro Assurance SPARK language, SPARK Pro	Static check
	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
6	Ada language, GNAT Pro for Ada, GNAT Pro Assurance SPARK language, SPARK Pro	Static check
7	Ada language, GNAT Pro for Ada, GNAT Pro Assurance SPARK language, SPARK Pro	Static check
8	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
9	Ada language, GNAT Pro for Ada, GNAT Pro Assurance	Run-time check[707]
	SPARK language, SPARK Pro	Static check
	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
10	SPARK language, SPARK Pro	Static check
	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
11	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
12	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]
	Ada Language, GNAT Pro for Ada, GNAT Pro Assurance	Run-time check[709]
	GNATstack (for preventing stack overflow)	Static check
13	Ada language, GNAT Pro for Ada, GNAT Pro Assurance SPARK language, SPARK Pro	Static check
14	Defects and Vulnerability Analyzer (in CodeSonar for Ada)	Static check[708]

[707] Depending on the source code, the GNAT Pro compiler may be able to guarantee that the check will always succeed and can thus avoid generating run-time code to detect violations.
[708] The static checks can result in false alarms (*false positives*), but the user can calibrate the tool to control the tradeoff between soundness (no false negatives) and precision (minimization of false positives).
[709] Exhausting dynamic memory raises the `Storage_Error` exception at run time. Ada does not require a general

150.9 Compliance Summary

Table 41 shows how AdaCore's technologies support the requirements in ECSS-E-ST-40C:

Table 41: Technology Support for ECSS-E-ST-40C Compliance

Technology	§5.4	§5.5	§5.6	§5.7	§5.8	§5.9	§5.10	§5.11	Annex U
Ada language	✓	✓			✓	✓	✓	✓	✓
SPARK language	✓	✓			✓		✓	✓	✓
GNAT Pro for Ada	✓	✓	✓	✓	✓		✓	✓	✓
SPARK Pro	✓	✓	✓		✓		✓	✓	✓
CodeSonar for Ada		✓	✓		✓		✓	✓	✓
GNAT Dynamic Analysis Suite		✓	✓		✓		✓	✓	
GNAT Pro Assurance	✓	✓	✓	✓	✓	✓	✓	✓	✓

garbage collector for storage reclamation, but several techniques can be used to prevent storage leaks:

- Ensure, through analysis or testing, that dynamic allocations occur only during startup (*elaboration time*) and not thereafter.
- Reclaim storage explicitly through Ada's `Unchecked_Deallocation` and ensure, through analysis or testing, that this does not create dangling references.
- Define a memory pool for a pointer type (*access type*) so that allocations of objects for that type only use that storage area, and through analysis or testing demonstrate that the pool is never exhausted. Ada's memory pool facility can be used to implement a reference counting strategy (for non-cyclic data structures) with automatic reclamation.

CHAPTER

ONE

COMPLIANCE WITH ECSS-Q-ST-80C

The ECSS-Q-ST-80C standard defines software product assurance requirements for the development and maintenance of space software systems. This chapter explains how AdaCore's products can help a supplier meet many of these requirements. The section numbers in braces refer to the relevant content in ECSS-Q-ST-80C.

151.1 Software product assurance programme implementation {§5}

151.1.1 Software product assurance programme management {§5.2}

Quality requirements and quality models {§5.2.7}

- "Quality models shall be used to specify the software quality requirements" {§5.2.7.1a}
  - The GNATmetric tool (see *GNATmetric* (page 2778)) in CodeSonar for Ada can show quality metrics related to the source code structure.
  - The GNATdashboard IDE tool (see *GNATdashboard* (page 2774)) can display software quality data.

151.1.2 Tools and supporting environment {§5.6}

Methods and tools {§5.6.1}

- **"Methods and tools to be used for all activities of the development cycle** ... shall be identified by the supplier and agreed by the customer" {§5.6.1.1a}
  - The GNAT Pro for Ada environment and any supplemental tools that are selected (e.g., CodeSonar for Ada, GNAT Dynamic Analysis Suite, SPARK Pro) should be listed.
- "The choice of development methods and tools shall be justified by demonstrating through testing or documented assessment that ... the tools and methods are appropriate for the functional and operational characteristics of the product, and ... the tools are available (in an appropriate hardware environment) throughout the development and maintenance lifetime of the product, ... the tools and methods are appropriate to the security sensitivity of the product as determined by the security analysis and as defined in the software security management plan" {§5.6.1.2a}
  - AdaCore can make available a variety of documentation showing that the selected tools are "appropriate for the functional and operational characteristics of the product", ranging from user manuals to qualification material relative to

other high-assurance software standards such as DO - 178C/ED - 12C[710] and EN 50128[711].

- AdaCore's *sustained branch* service for its GNAT Pro for Ada Assurance product (see *Sustained Branches* (page 2770)) can guarantee that the toolchain is maintained throughout the product lifetime.
- AdaCore's SPARK Pro environment (see *Static Verification: SPARK Pro* (page 2766)) can be used to demonstrate security properties such as correct information flows and, for software at the highest security levels, compliance with formally specified requirements.

Development environment selection {§5.6.2}

- "The software development environment shall be selected according to the following criteria: 1. availability; 2. compatibility; 3. performance; 4. maintenance; 5. durability and technical consistency with the operational environment; 6. the assessment of the product with respect to requirements, including the criticality category; 7. the available support documentation; 8. the acceptance and warranty conditions; 9. the conditions of installation, preparation, training and use; 10. the maintenance conditions, including the possibilities of evolutions; 11. copyright and intellectual property rights constraints; 12. dependence on one specific supplier; 13. the assessment of the product with respect to the security sensitivity level of the products; 14. compliance with appropriate security requirements due to organizational or national security regulations, policies or directives." {§5.6.2.1a}
  - AdaCore tools directly satisfy these criteria. The availability of qualification material for specific tools (GNATcheck, GNATprove, GNATstack) contributes to criterion 6, and the *sustained branch* service for GNAT Pro for Ada Assurance supports criteria 4, 7 and 10. AdaCore tools come with source code and flexible licensing, mitigating the issues noted in criteria 11 and 12. CodeSonar for Ada, SPARK, and the GNATfuzz tool in the GNAT Dynamic Analysis Suite facilitate demonstrating the relevant security properties (criteria 13 and 14).

151.2 Software process assurance {§6}

151.2.1 Requirements applicable to all software engineering processes {§6.2}

Handling of critical software {§6.2.3}

- "The supplier shall define, justify and apply measures to assure the dependability and safety of critical software.... These measures can include: ... use of a 'safe subset' of programming language; use of formal design language for formal proof; 100% code branch coverage at unit testing level; ... removing deactivated code or showing through a combination of analysis and testing that the means by which such code can be inadvertently executed are prevented, isolated, or eliminated; use of dynamic code verification techniques." {§6.2.3.2a}
  - Ada's pragma `Restrictions` and pragma `Profile`, together with GNATcheck from CodeSonar for Ada, can enforce a coding standard for Ada (in effect a 'safe subset'). See *GNAT Pro Enterprise* (page 2769) and *GNATcheck* (page 2778).
  - The SPARK language serves as a safe subset of full Ada, and a formal design language for formal proof.

[710] *DO-178C/ED-12C: Software Considerations in Airborne Systems and Equipment Certification*. RTCA and EUROCAE, December 2011.
[711] *EN 50128/A2: Railway applications – Communications, signalling and processing systems – Software for railway control and protection systems*. CENELEC, July 2020.

  - SPARK Pro uses proof technology that can demonstrate a program's conformance with formally specified requirements.
  - GNATcoverage can report code coverage up to MC/DC at the source level.
  - The Defects and Vulnerability Analyzer in CodeSonar for Ada can detect unreachable code, including deactivated code.
  - The Ada language and the GNAT Pro Ada development environment allow contracts to be verified either statically or with run-time checks and thus facilitate dynamic code verification.

Verification {§6.2.6}

- "The completion of actions related to software problem reports generated during verification shall be verified and recorded." {§6.2.6.4a}
  - GNAT Pro for Ada Assurance, and its Sustained Branch service, help support compliance.
- "Software containing deactivated code shall be verified specifically to ensure that the deactivated code cannot be activated or that its accidental activation cannot harm the operation of the system." {§6.2.6.5a}
  - The Defects and Vulnerability Analyzer in CodeSonar for Ada can detect unreachable code, including deactivated code.

Software security {§6.2.9}

- "The supplier shall identify the methods and techniques for the software security analysis." {§ 6.2.9.3a}
  - The Ada and SPARK languages, GNAT Pro for Ada, CodeSonar for Ada, the GNAT Dynamic Analysis Suite, and the SPARK Pro toolset help meet this requirement.
- "Based on the results of the software security analysis, the supplier shall apply engineering measures to reduce the number of security sensitive software components and mitigate the risks associated with security sensitive software." {§ 6.2.9.4a}
  - Code modularization in Ada and SPARK can be used to minimize the number of security sensitive components, and to localize and encapsulate them in modules (packages) with compile-time enforcement of data consistency. Checks performed by the GNAT Pro and SPARK Pro tools help mitigate security risks, while hybrid verification can combine formal analysis (for high security components in SPARK) with traditional testing methods.

Handling of security sensitive software {§ 6.2.10}

- "The supplier shall define and implement measures to avoid propagation of failures, including the ones caused by deliberate action, between software components." {§ 6.2.10.1a}
  - The Ada language provides features that support this requirement for components in the same address space. Failures can be modeled by exceptions, and software components that need to interact synchronously or asynchronously can be modeled by tasks. (A failure in one component may be due to a device malfunction and is not necessarily security related, but it needs to be handled in a way that does not compromise security or other mission requirements.) If the failure (exception) occurs in an Ada task, then an appropriate style is for the task to take corrective measures by handling that exception and/or to report the failure so that a separate component can take further actions. If the task terminates as a result of the exception, the effect is localized; the failure that triggered the termination does not propagate to other components.

- The SPARK language and SPARK Pro can help by ensuring that failures do not occur (proving the Absence of Run-Time Errors).

151.2.2 Requirements applicable to individual software engineering processes or activities {§6.3}

Coding {§6.3.4}

- "Coding standards (including security, consistent naming conventions and adequate commentary rules) shall be specified and observed." {§6.3.4.1a}
  - Ada's `Restrictions` and `Profile` pragmas, together with AdaCore's GNATcheck tool (see section *GNATcheck* (page 2778)), can define and enforce a coding standard.
  - The SPARK language can serve as a coding standard.
- "The tools to be used in implementing and checking conformance with coding standards shall be identified in the product assurance plan before coding activities start." {§6.3.4.3a}
  - GNATcheck and SPARK Pro are relevant tools for this activity.
- "The supplier shall define measurements, criteria and tools to ensure that the software code meets the quality and security requirements." {§6.3.4.6a}
  - The GNATmetric tool (see *GNATmetric* (page 2778)) can be used to report quality data related to the source code structure.
- "Synthesis of the code analysis results and corrective actions implemented shall be described in the software product assurance reports." {§6.3.4.7a}
  - GNATdashboard (see *GNATdashboard* (page 2774)) can be used to synthesize and summarize code quality metrics.

Testing and validation {§6.3.5}

- "Testing shall be performed in accordance with a strategy for each testing level (i.e. unit, integration, validation against the technical specification, validation against the requirements baseline, acceptance), ..." {§6.3.5.1a}
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement for unit testing.
- "Based on the dependability and safety criticality, and the security sensitivity of the software, test coverage goals for each testing level shall be agreed between the customer and the supplier and their achievement monitored by metrics ...." {§6.3.5.2a)
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement.
- "Test coverage shall be checked with respect to the stated goals." {§6.3.5.5a}
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement.
- "The test coverage of configurable code shall be checked to ensure that the stated requirements are met in each tested configuration." {§6.3.5.7a}
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement.
- "Test tool development or acquisition ... shall be planned for in the overall project plan." {§6.3.5.24a}

  - The tools in AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) are candidates for consideration in test tool acquisition.

- "Software containing deactivated code shall be validated specifically to ensure that the deactivated code cannot be activated or that its accidental activation cannot harm the operation of the system." {§6.3.5.30a}
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement by detecting non-covered code that is intended (and can be categorized) as deactivated.
- "Software containing configurable code shall be validated specifically to ensure that unintended configuration cannot be activated at run time or included during code generation". {§6.3.5.31a}
  - AdaCore's GNAT Dynamic Analysis Suite (GNATtest, GNATcoverage, GNATfuzz) can help meet this requirement by detecting configurable code that, because of incorrect configuration settings, was unintentionally included during code generation.

Maintenance {§6.3.9}

- "The maintenance plans and procedures shall include the following as a minimum: 1. scope of maintenance; 2. identification of the first version of the software product for which maintenance is to be done; 3. support organization; 4. maintenance life cycle; 5. maintenance activities; 6. quality measures to be applied during the maintenance; 7. security measures to be applied during the maintenance. 8. maintenance records and reports." {§6.3.9.4a}
  - The *sustained branch* service of AdaCore's GNAT Pro Assurance product can help meet this requirement.
- "Maintenance records shall be established for each software product ...." {§6.3.9.7a}
  - AdaCore's ticket system, which is part of the standard support in all product subscriptions, provides an audit trail for problem reports / resolution.
  - The *sustained branch* service includes special maintenance accommodation for dealing with problems that relate to software safety.

151.3 Software product quality assurance {§7}

151.3.1 Product quality objectives and metrication {§7.1}

Assurance activities for product quality requirements {§7.1.3}

- "The supplier shall define assurance activities to ensure that the product meets the quality requirements as specified in the technical specification" {§7.1.3a}
  - Any of AdaCore's tools could potentially contribute to meeting this requirement, depending on the nature of the metrics that have been defined, and the GNATdashboard tool can integrate the metrics in a meaningful way.
  - Use of the SPARK language, and formal demonstration of absence of runtime errors, support this requirement.

Basic metrics {§7.1.5}

- "The following basic products metrics shall be used: size (code); complexity (design, code); fault density and failure intensity; test coverage; number of failures." {§7.1.5a}

  - The GNATmetric, GNATtest, and GNATcoverage tools in the GNAT Dynamic Analysis Suite directly help to meet this requirement.

151.3.2 Product quality requirements {§7.2}

Design and related documentation {§7.2.2}

- "The software shall be designed to facilitate testing." {§7.2.2.2a}
  - The Ada language encourages and supports the use of sound software engineering principles such as modular design and structured programming, which makes the code easier to test.
  - The contract facility in Ada and SPARK supports verification by both static analysis and testing.
- "Software with a long planned lifetime shall be designed with minimum dependency on the operating system and the hardware in order to aid portability." {§7.2.2.3a}
  - The Ada language has abstracted away the specifics of the underlying operating system and hardware through standard syntax and semantics for features such as concurrency, memory management, exception handling, and I/O. As a result, Ada programs can often be ported across different processor architectures and operating systems by simply recompiling, with minimal or no source code changes needed.

Test and validation documentation {§7.2.3}

- "Test procedures, data and expected results shall be specified." {§ 7.2.3.4a}
  - The GNATtest and GNATfuzz tools in the GNAT Dynamic Analysis Suite help meet this requirement.
- "For any requirements not covered by testing a verification report shall be drawn up documenting or referring to the verification activities performed." {§7.2.3.6a}
  - In many cases where verification cannot be achieved by testing, SPARK Pro may be able to provide convincing alternative verification evidence (for example, a robustness demonstration by proof that an out-of-range or otherwise non-valid input will never be passed to the unit being verified).

151.4 Compliance Summary

Table 42 shows how AdaCore's technologies support the requirements in ECSS-Q-ST-80C:
